APPROVAL PACKAGE FOR:

APPLICATION NUMBER

19-386

Approval Letter(s)

DEPARTMENT OF HEALTH & HUMAN SERVICES

Public Health Service

Food and Drug Administration
Rockville MD 20857

NDA 19-386

DEC 31 1986

Dupont Critical Care, Inc.
Attention: Kenneth G. Kasses, Ph.D.
1600 Waukegan Road
Waukegan, IL 60085

Dear Dr. Kasses:

Please refer to your December 31, 1984 new drug application submitted under section 505(b)(1) of the Federal Food, Drug, and Cosmetic Act for Brevibloc (esmolol HCl) Injection 250 mg/mL in 10 mL ampules.

We also acknowledge receipt of your amendment dated December 29, 1986.

We have completed the review of this application including the submitted draft labeling and have concluded that adequate information has been presented to demonstrate that the drug product is safe and effective for use as recommended in the enclosed marked-up draft labeling. Accordingly, the application is approved effective on the date of this letter.

We acknowledge your commitment made in our December 30, 1986 meeting to conduct post marketing studies to explore the prominent hypotensive effect of esmolol. We suggest comparison of the hemodynamic effects of esmolol to those of propranolol, atenolol and metoprolol. Further details of such a study can be discussed with the Division of Cardio-Renal Drug Products.

Please submit twelve copies of the FPL as soon as available. Please individually mount seven of the copies on heavy weight paper or similar material. For administrative purposes this submission should be designated "FPL Supplement" to the approved NDA 19-386. Approval of this supplement by FDA is not required before the labeling is used.

The final printed labeling (FPL) must be identical to the marked-up draft labeling. Marketing the product with FPL that is not identical to the draft labeling may render the product misbranded and an unapproved new drug.

At the time of the next printing, please increase the type size of esmolol HCl where ever it appears on the outer carton.

Should additional information relating to the safety and effectiveness of the drug become available prior to our receipt of the final printed labeling, revision of that labeling may be required.

In addition, we would appreciate your submitting copies of the introductory promotional material that you propose to use for this product. Please submit one copy to the Division of Cardio-Renal Drug Products and a second, along with a copy of the package insert, directly to:

Division of Drug Advertising and Labeling, HFN-240
Room 108-04
5600 Fishers Lane
Rockville, Maryland 20857

Please submit all proposed materials in draft or mock-up form, not final print. Also, please do not use form FD-2253 for this submission; this form is for routine use, not proposed materials.

Please submit one market package of the drug when it is available.

We remind you that you must comply with the requirements for an approved NDA set forth under 21 CFR 314.80 and 314.81.

If you have any questions, please contact:

Ms. Constance Burner Henry
Consumer Safety Officer
(301) 443-4730

Sincerely yours,

Robert Temple, M.D.
Director
Office of Drug Research and Review
Center for Drugs and Biologics

Enclosure

BREVIBLOC[®] INJECTION

(esmolol hydrochloride)

10 mL Ampul — 2.5 g

NOT FOR DIRECT INTRACARDIAC INJECTION. BREVIBLOC[®] MUST BE DILUTED PRIOR TO OR INTRAVENOUS INJECTIONS AND ADMINISTRATION SOLUTIONS.

DESCRIPTION

BREVIBLOC[®] (esmolol HCl) is a beta₁-selective (cardioselective) adrenergic receptor antagonist with a very short duration of action (elimination half-life is approximately 9 minutes) (esmolol HCl).

1-(3-Methyl-5-(2-hydroxy-3-(propoxyphenyl)hydroxyethyl)butyl)pyrrolidine hydrochloride and has the following structure:

Esamolol HCl has the empirical formula $\text{C}_{21}\text{H}_{35}\text{NO}_2$ and a molecular weight of 331.6. It has one asymmetric center and exists as an enantiomeric pair. Esamolol HCl is a white to off-white, hygroscopic powder. It is a relatively hydrophilic compound which is very soluble in water and freely soluble in alcohol. Its partition coefficient (octanol/water) at pH 7.0 is 0.42 compared to 17.0 for propranolol. BREVIBLOC[®] (esmolol HCl) is a clear, colorless to light yellow, sterile, isotonic, aqueous solution in which various buffers are used. It has a pH range of 3.8 to 5.5.

2.5 g, 10 mL Ampul — Each mL contains 250 mg esmolol HCl in 25% Propylene Glycol USP, 25% Alcohol USP and Water for Injection USP, buffered with 17.0 m, Sodium Acetate USP, and 0.00713 m, Glacial Acetic Acid USP. Sodium hydroxide and hydrochloric acid added as necessary to adjust pH.

Clinical Pharmacology

BREVIBLOC[®] (esmolol HCl) is a beta₁-selective (cardioselective) adrenergic receptor blocking agent with rapid onset, a very short duration of action, and no significant intrinsic sympathomimetic or membrane stabilizing activity. Its elimination half-life after intravenous injection is approximately 9 minutes. BREVIBLOC[®] exerts its beta₁-selective, receptor-mediated effects in various tissues. Due to the preferential effect on the sinoatrial node and higher doses it exerts its effect on the bronchial and vascular musculature.

Pharmacokinetics and Metabolism

BREVIBLOC[®] (esmolol HCl) is rapidly metabolized by hydrolysis of the ester linkage chiefly by the esterase of the cytosol of red blood cells and not by plasma cholinesterase or red cell acetylcholinesterase. Total body clearance in man has been found to be about 20 L/min, which is greater than cardiac output, thus the metabolism of BREVIBLOC[®] is not limited by the rate of blood flow to metabolizing tissues such as the liver or affected by hepatic or renal blood flow. BREVIBLOC[®] has a rapid distribution half-life of about 7 minutes and an elimination half-life of about 9 minutes. Steady-state plasma levels of BREVIBLOC[®] for doses from 50-300 mg/kg given are obtained within five minutes. Steady-state is reached in about 30 minutes without the loading dose. Steady-state plasma levels of BREVIBLOC[®] are dose-dependent over the range 0.1-3.0 mg/kg. Steady-state plasma levels are dose-independent over this range. Steady-state plasma levels are maintained during continuous infusion. The plasma level of the drug can be adjusted to the desired level by adjusting the infusion rate and rapidly eliminated by discontinuing the infusion.

Consistent with the high rate of blood level metabolism of BREVIBLOC[®], less than 2% of the drug is excreted unchanged in the urine within 24 hours of the end of infusion, approximately 71-86% of the drug has been excreted in the urine as the acid metabolite of BREVIBLOC[®].

Metabolism of BREVIBLOC[®] results in the formation of the corresponding free acid and ethanol. The free metabolite has been shown in animals to have about 1/10000 the activity of esmolol and as normal volunteers its blood levels do not contribute to the level of beta blockade. The acid metabolite has an elimination half-life of about 3.7 hours and is excreted in the urine with a clearance approximately equivalent to the glomerular filtration rate. Excretion of the acid metabolite is significantly enhanced in patients with renal disease with the elimination half-life increased to about ten fold that of normal, and plasma levels considerably elevated.

Metabolic blood levels measured in man. BREVIBLOC[®] for up to 6 hours at 300 mcg/kg/min and 24 hours at 150 mcg/kg/min, an approximate endogenous level and were less than 2% of levels usually associated with metabolic toxicity.

BREVIBLOC[®] has been shown to be 55% bound to human plasma protein while the acid metabolite is only 14% bound.

Pharmacodynamics

Cardiac pharmacodynamic studies in normal volunteers have confirmed the beta₁-selective activity of BREVIBLOC[®] (esmolol HCl) showing reduction in heart rate of rest and during exercise and attenuation of exercise heart rate increase in heart rate. Blood levels of BREVIBLOC[®] have been shown to correlate with extent of beta blockade. After termination of infusion, beta-adrenergic recovery from beta blockade is observed in 10-20 minutes.

In human electrophysiologic studies, BREVIBLOC[®] produced effects typical of a beta₁ blocker: a decrease in the heart rate, increase in sinus cycle length, prolongation of the sinus node recovery time, prolongation of the AV interval during normal sinus rhythm and during atrial pacing, and an increase in atrioventricular conduction cycle length.

In patients undergoing radiologic angiography, BREVIBLOC[®] at a dosage of 200 mcg/kg given produced reductions in heart rate, systolic blood pressure, rate pressure product, left ventricular stroke volume and stroke work index and right ventricular stroke volume and stroke work index. During exercise, BREVIBLOC[®] produced reductions in heart rate, rate pressure product and cardiac index which were also similar to those produced by propranolol but produced a significantly larger fall in systolic blood pressure. In patients undergoing cardiac catheterization, the maximum decrease in heart rate of 300 mcg/kg of BREVIBLOC[®] produced similar effects, and in addition there were small, transient increases in the left ventricular and systemic pressure and pulmonary capillary wedge pressure. At thirty minutes after the discontinuation of BREVIBLOC[®] infusion, all of the hemodynamic parameters had returned to pretreatment levels.

The relative cardioselectivity of BREVIBLOC[®] was demonstrated in 10 healthy sedentary patients. In patients receiving BREVIBLOC[®] (100, 200 and 300 mcg/kg) administered subcutaneously, there was a significant increase in heart rate, average increase compared to placebo. At 300 mcg/kg given, BREVIBLOC[®] produced slightly enhanced bronchodilation sensitivity to 0.1 mg of albuterol. These effects were not clinically significant and BREVIBLOC[®] was well tolerated by all subjects, but of the patients who received intravenous esmolol, and at a dosage of 1 mg/kg, two experienced significant, symptomatic bronchospasm requiring bronchodilator treatment. One other patient who received placebo also experienced dry or reduced bronchospasm. No adverse pulmonary effects were observed in patients with COPD who received therapeutic dosages of BREVIBLOC[®] for treatment of supraventricular tachycardia (51 patients) or in perioperative settings (12 patients).

Supraventricular Tachycardia

In two multicenter, randomized, double-blind, controlled comparisons of BREVIBLOC[®] (esmolol HCl) with placebo and propranolol, maintenance doses of 50 to 300 mcg/kg/min of BREVIBLOC[®] were found to be more effective than placebo and about as effective as propranolol, 3-6 mg given by bolus injections in the treatment of supraventricular tachycardia. In patients with atrial flutter, the majority of these patients developed sinus rhythm. In patients with supraventricular tachycardia, about 50-70% of the patients treated with BREVIBLOC[®] had a desired therapeutic effect (either a 20% reduction in heart rate, a decrease in heart rate to less than 100 bpm, or a rate conversion to sinus rhythm) and about 50% of those who responded did so at a dosage of 200 mcg/kg/min or less. The average effective dosage of BREVIBLOC[®] was approximately 110 mcg/kg/min in the two studies. Other medications (including beta-blockers) were given concomitantly with BREVIBLOC[®] in the comparison with propranolol, about 50% of patients in both the BREVIBLOC[®] and propranolol groups were on concomitant drugs. Response rates were slightly higher with both beta-blockers in the drug-treated patients.

In all studies, significant decreases of blood pressure occurred in 70-90% of patients, identified either as adverse reactions reported by investigators, or by observation of systemic pressure less than 90 mmHg or diastolic pressure less than 50 mmHg. About 17% of the patients have been symptomatic (dizziness, lightheadedness, or syncope) at about 17% of patients, but symptoms were not clinically significant. In comparison to placebo, BREVIBLOC[®] was found to be more effective in the treatment of supraventricular tachycardia. The response rate was significantly higher with BREVIBLOC[®] (53% vs. 37%). The hypotension was rapidly reversible with decreased infusion rate or after discontinuation of therapy with BREVIBLOC[®]. For both BREVIBLOC[®] and propranolol, hypotension was reported less frequently in patients receiving concomitant drugs.

INDICATIONS AND USAGE

Supraventricular Tachycardia

BREVIBLOC[®] (esmolol HCl) is indicated for the rapid control of ventricular rate in patients with atrial flutter or atrial fibrillation in perioperative, postoperative or other emergent circumstances when other forms of ventricular rate with a short-acting agent is desirable. BREVIBLOC[®] is also indicated in non-emergent circumstances where transfer to another agent is anticipated.

CONTRAINDICATIONS

BREVIBLOC[®] (esmolol HCl) is contraindicated in patients with sinus bradycardia, heart block greater than first degree, cardiogenic shock or overt heart failure (see WARNINGS).

WARNINGS

Hypotension: In clinical trials 20-50% of patients treated with BREVIBLOC[®] (esmolol HCl) have had hypotension, generally defined as systemic pressure less than 90 mmHg and/or diastolic pressure less than 50 mmHg. About 17% of the patients have been symptomatic (dizziness, lightheadedness, or syncope). Hypotension can occur at any dose but is dose-related as the doses beyond 200 mcg/kg/min are not recommended. Patients should be closely monitored, especially if treatment based on pressure is used. Discontinuation of drug or reduction of infusion rate reverses hypotension, usually within 30 minutes.

Cardiac Failure: Symptomatic circulatory depression is necessary in supporting circulatory function in congestive heart failure, and beta-blockade can have the potential hazard of further depressing myocardial contractility and precipitating more severe failure. Continued administration of the myocardium with beta-blockers agents may result in a further fall in stroke volume, lead to cardiac failure. At the first sign or symptom of impending cardiac failure, the dosage should be reduced or BREVIBLOC[®] should be withdrawn. Although this dosage adjustment or withdrawal may be sufficient because of the short elimination half-life of BREVIBLOC[®], symptomatic treatment may also be indicated. (See Dosage.)

Bradycardia: Bradycardia is a common side effect of BREVIBLOC[®]. Patients with bradycardia should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. Bradycardia may be a sign of heart failure, especially in patients with congestive heart failure. BREVIBLOC[®] may be used with caution in patients with bradycardia. However, when used, particularly in patients with bradycardia, BREVIBLOC[®] should be given with caution. In the event of bradycardia, the patient should be monitored closely. However, when used, particularly in patients with

When digoxin and BREVELOC® (metoprolol HCl) are concurrently administered intravenously to normal volunteers, there was a 10-20% increase in digoxin blood levels of some time points. Digoxin did not affect BREVELOC® pharmacokinetics. When the venous sinus and BREVELOC® were administered simultaneously to normal volunteers, no effect on digoxin blood levels was seen. For BREVELOC®, steady-state blood levels were increased by 50% to 60% presence of digoxin for the pharmacokinetic parameters studied.

The effect of BREVELOC® on the duration of succinylcholine-induced neuromuscular blockade® was studied in patients undergoing surgery. The onset of neuromuscular blockade by succinylcholine was unaffected by BREVELOC®, but the duration of neuromuscular blockade was prolonged from 8 minutes to 9 minutes. Although the interaction observed in these studies do not appear to be of major clinical importance, BREVELOC® should be treated with caution in patients being treated concurrently with digoxin, morphine, succinylcholine or narcotic.

Cardiovascular, Hemodynamic, Impairment of Fertility

Because of its short term usage as an anesthetic, no study of reproductive performance studies have been conducted with BREVELOC®.

Prepregnancy Category C

Toxicity studies in rats at intravenous doses of BREVELOC® up to 3000 mcg/kg/day (10 times the maximum human maintenance dosage) for 30 days prior to mating produced no evidence of maternal toxicity, embryotoxicity or fetotoxicity. While a dosage of 10 000 mcg/kg/day produced maternal toxicity and mortality, no adverse developmental changes up to 1000 mcg/kg/day for 30 days daily produced no evidence of maternal toxicity, embryotoxicity or fetotoxicity. While 2000 mcg/kg/day produced maternal mortality and increased loss rate.

There are no adequate and well-controlled studies in pregnant women. BREVELOC® should be used during pregnancy only if the potential benefits justify the potential risk to the fetus.

Lactating Mothers

It is not known whether BREVELOC® is excreted in human milk. However, caution should be exercised when BREVELOC® is administered to a nursing woman.

Pediatric Use

The safety and effectiveness of BREVELOC® in children have not been established.

ADVERSE REACTIONS

Supraventricular Tachycardia

The following adverse reaction rates are based on use of BREVELOC® (metoprolol HCl) at almost 400 clinical trial patients with supraventricular tachycardia. In addition, over 100 patients have been treated in clinical studies at other dosages. The most important adverse effect has been hypotension (see Warnings) and bradycardia (see Precautions).

Conduction System - Symptomatic bradycardia (diastolic < 50 mmHg) occurred in 12% of patients and therapy was discontinued in about 11%. About half of whom were asymptomatic. Hypotension (systolic < 90 mmHg) occurred in about 25% of patients. Hypotension resolved during BREVELOC® infusion in 63% of these patients and within 30 minutes after discontinuation of infusion in 80% of the remaining patients. Discontinued accompanied hypotension in 10% of patients. Peripheral edema occurred in approximately 1% of patients. Prolonged QTc interval (more than 440 msec) occurred in less than 1% of patients. Chest pain (angina) occurred in about 1% of patients. Chest pain (angina) occurred in about 1% of patients. In two patients without supraventricular tachycardia but with various coronary artery disease (past myocardial infarction or unstable angina) severe myocardial infarction (myocardial infarction) has developed, reversible in both cases with discontinuation of treatment.

Other Heart Issues - Dizziness has occurred in 3% of patients, orthostatic hypotension in 2%, conduction blockade, and syncope in about 2% and fatigue in about 1% of patients. Prolonged QTc interval (more than 440 msec) occurred in about 1% of patients. Syncope, orthostatic hypotension, dizziness, and fatigue were reported in less than 1% of patients. One brief (30 second) episode of grand mal seizure has been reported.

Respiratory - Bronchospasm, wheezing, dyspnea, nasal congestion, rhinitis, and sinusitis have each been reported in less than 1% of patients.

Neurological - Headache has occurred in 7% of patients. Vertigo has occurred in about 1% of patients. Dizziness, somnolence, dry mouth, and abnormal gait/coordination have each occurred in less than 1% of patients. Taste perversion has also been reported.

Eye Issues - Blurred vision has occurred in 1% of patients. Diplopia, dry eyes, and lacrimation were reported in about 0.5% of patients. Edema, conjunctivitis, and tearing of the conjunctiva have each occurred in less than 1% of patients.

Renal Issues - Urinary retention (acute or chronic) and urinary incontinence were reported in about 0.5% of patients. Edema, conjunctivitis, and tearing of the conjunctiva have each occurred in less than 1% of patients. Urinary retention (acute or chronic), abnormal vision, conjunctivitis, and tearing of the conjunctiva have each occurred in less than 1% of patients.

OVERDOSE

Acute Toxicity

A single case of accidental overdosage with BREVELOC® (metoprolol HCl) has occurred at a 1000 mcg/kg/day dose of BREVELOC® instead of the recommended 100 mcg/kg/day. The patient was asymptomatic and had a normal ECG. The patient was treated with oral fluids and activated charcoal. The patient's heart rate and blood pressure were decreased and the patient became drowsy but could be aroused. The infusion rate of BREVELOC® was decreased to 5 mcg/kg/day and over the next eight hours the patient's rhythm converted to normal sinus rhythm and the patient started feeling better. Hypotension persisted for a period of two minutes after discontinuing the dose of BREVELOC®. The symptoms disappeared 15 minutes following discontinuation of BREVELOC®.

Because of its propensity to block β_1 and β_2 receptors, the high risk in the event of toxicity should be to discontinue BREVELOC® administration. Then, based on the pharmacologic actions, the following general measures should be considered:

Respiratory - Intravenous administration of atropine or another anticholinergic drug.

Cardiovascular - Intravenous administration of a beta₁ stimulating agent and/or a strong β_2 agonist.

Central Nervous System - Intravenous administration of a barbiturate and/or diazepam. Hypotension in which resulting from vasodilation should be treated with administration of dopamine, dobutamine, norepinephrine or adrenergic may be considered.

DIAGNOSIS AND ADMINISTRATION

NOT FOR DIRECT INTRAVENOUS INJECTION BREVELOC® IS A CONCENTRATED POTENT DRUG WHICH MUST BE DILUTED PRIOR TO ITS INFUSION. BREVELOC® SHOULD NOT BE ADDED TO ANY SOLUTIONS CONTAINING: BREVELOC® AND A NOT BE MIXED WITH OTHER DRUGS PRIOR TO DILUTION IN A SUITABLE INTRAVENOUS FLUID. (See Compatibility Section below.)

Note: Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration whenever solution and container permit. **Warnings:** Anaphylactoid reactions have been reported with the intravenous fluid used in these cases. Compatibility with commonly used intravenous fluids also see the contents of this (2) Ampule of BREVELOC® (each containing 2.5 g (50 mg) metoprolol tartrate) in this package. This package contains a concentration of 10 mg/ml. The diluted solution is stable for at least 24 hours at room temperature. **Note:** Containers of BREVELOC® contain less than 10 mg/ml and may be used to produce a solution in a suitable intravenous fluid. BREVELOC® has, however, been used for and when administered via a central vein.

Supraventricular Tachycardia

In the treatment of supraventricular tachycardia, the response to BREVELOC® usually occurs within the range of 40 to 200 mcg/kg/day. The average effect was a decrease in heart rate of approximately 100 mcg/kg/day. Although dosages as low as 25 mcg/kg/day have been adequate in some patients, dosages as high as 300 mcg/kg/day may be used. The effect is dose dependent and an increased rate of adverse effects, and are not recommended. Change of BREVELOC® in supraventricular tachycardia must be discontinued by the patient in which each may consist of a loading dose, or followed by a maintenance dosage. The initial treatment of a patient with supraventricular tachycardia, whenever a loading dose of 100 mcg/kg/day of BREVELOC® for one minute followed by a 4 hour maintenance infusion of 50 mcg/kg/day. An adequate therapeutic effect is not observed within five minutes, repeat the same loading dosage and then with a maintenance infusion increased to 100 mcg/kg/day.

Continuous infusion procedure as above repeating loading infusion (500 mcg/kg/day for 1 minute), increasing maintenance infusion by increments of 50 mcg/kg/day (for 4 minutes). As the desired heart rate or a safety end-point is reached blood pressure is monitored and if necessary adjusted. Once the desired heart rate and blood pressure are maintained, the infusion rate may be reduced to 25 mcg/kg/day or lower. As it is desired, normal arterial blood pressure should last 5 to 10 minutes. Maintenance dosages above 200 mcg/kg/day have not been shown to have significantly increased benefits, and the safety of dosages above 300 mcg/kg/day has not been studied.

In the event of an adverse reaction, the dosage of BREVELOC® may be reduced or discontinued. If a load infusion procedure is necessary, an alternative infusion rate should be used. The use of lactated Ringers should be avoided.

Aggravated reaction of BREVELOC® in patients has not been reported to produce the untoward effects which may occur with abrupt withdrawal of beta-blockers following chronic use in coronary artery disease (CAD) patients. However, caution should still be used in abruptly discontinuing dosages of BREVELOC® in CAD patients.

After achieving an adequate control of the heart rate and a stable clinical status in patients with supraventricular tachycardia, transition to alternative antiarrhythmic agents such as propafenone, digoxin or verapamil may be appropriate. A recommended procedure for such a transition is given below but the physician should carefully consider the following instructions for the alternative agent selected:

Alternative Agent	Dosage
Propafenone hydrochloride	10-20 mg, q 6h
Digoxin	0.125-0.5 mg q 6h (p.o. or i.v.)
Verapamil	60 mg q 6h

The dosage of BREVELOC® should be reduced as follows:

1. Thirty minutes following the last dose of the alternative agent, reduce the infusion rate of BREVELOC® by one-half (50%).

2. Following the second dose of the alternative agent, monitor the patient's response and if satisfactory control is maintained for the first hour, discontinue BREVELOC®.

The use of solutions of BREVELOC® up to 24 hours has been used documented. In addition, based data from 24-48 hrs (see Warnings) indicate that BREVELOC® is well tolerated up to 48 hours.

Compatibility with Commonly Used Intravenous Fluids

BREVELOC® (metoprolol HCl) INJECTION was tested for compatibility with eight commonly used intravenous fluids at a final concentration of 10 mg (metoprolol HCl) per mL. BREVELOC® INJECTION was found to be compatible with the following solutions and was stable for at least 24 hours at controlled room temperature or under refrigeration.

- Dextrose 5% Injection, USP
- Dextrose 5% in Ringer's Injection
- Dextrose 5% and Sodium Chloride 0.45% Injection, USP
- Dextrose 5% and Sodium Chloride 0.9% Injection, USP
- Lactated Ringer's Injection, USP
- Sodium Chloride 0.9% Injection, USP
- Sodium Chloride 0.3% Injection, USP

BREVELOC® INJECTION was NOT compatible with Sodium Bicarbonate 8.4% Injection, USP.

HOW SUPPLIED

BREVELOC® (metoprolol HCl) INJECTION - 2.5 g (250 mg/mL) is supplied in 10 mL Ampules

NDC 0094-0025-10 Box of 10

STORAGE: CONTROLLED ROOM TEMPERATURE 15°-30°C. Freezing does not adversely affect the product, but exposure to elevated temperatures should be avoided.

MEMORANDUM

DEPARTMENT OF HEALTH & HUMAN SERVICES
Public Health Service
Food and Drug Administration
Center for Drugs and Biologics

Date : December 29, 1986

From : Director, Office of Drug Research and Review (HFN-100)

Subject: Esmolol, NDA 19-386

To : Director, Division of Cardio-renal Drug Products (HFN-110)

This is, as you have indicated repeatedly in word and action, a relatively close decision. There is no doubt that esmolol can control ventricular response, at the cost of quite frequent hypotension, and can prevent the rise in heart rate and systolic blood pressure accompanying intubation and some other peri-surgical maneuvers, in this situation with very few side effects.

As you point out, the frequency of hypotension seems greater than expected for a beta-blocker and, indeed, hypotension was much more frequent with esmolol than propranolol in a direct comparison (Study 4).

	n = 60 Esmolol	n = 63 Propranolol
Reported symptomatic	4	1
Reported Asymptomatic	19	3
Total by "criteria"	27	10
Criteria plus reports	34	11

Esmolol is cardioselective, a modest advantage. We have never detected a difference in BP effects between selective and non-selective agents but, in theory, there should be one. The selective agent does not block the peripheral beta-2 dilating effects of circulating catecholamines, while the non-selective agent does, potentially "unmasking" alpha-stimulant (constricting) effects of endogenous catecholamines and maintaining blood pressure. Of course, there is still the question of why we don't see this all the time. Perhaps some reason that catecholamines are especially important to maintaining BP in the SVT setting. It may also be the other drugs present in the perioperative setting render this effect unimportant or it may be that in that setting catecholamines are high and of significance only at those times

(e.g., intubation) when they tend to raise heart rate and BP excessively; the extra vasodilating effect of esmolol is then seen as part of the beneficial effect on HR and BP.

A. Control of SVT

I think the views of the Cardio-Renal Advisory Committee should be given considerable weight, as you have done, in weighing the benefits and risks of esmolol in the SVT setting. The hypotension, while notable and certainly a factor that makes esmolol difficult to use (as does the need to give it by carefully titrated intravenous infusions), is readily reversible and usually asymptomatic. According to the Table I added to p. 67 of the SBA, while evidence of hypotension was present in 20-50% of patients only 6-13% of patients were symptomatic from it. In a direct comparison with propranolol, esmolol did not need to be stopped significantly more often than propranolol. While there were nominally 15 discontinuations due to hypotension in 7 of these there was also a lack of therapeutic response leaving only 8 cases of clear-cut discontinuation due to an adverse effect. There were 6 discontinuations from the propranolol group, for worsened CHF (2), sinus bradycardia (1), and nausea (3), alone (1) or accompanied by hypotension (1), or vomiting and headache (1). All-in all, then, the hypotension, while a management problem, did not result in a significantly greater rate of discontinuations.

The hypotension is also, under the closely monitored circumstances in which the drug is given, not unduly dangerous. There is no SVT patient described in the MNR (covering the original submission and the first safety update) or reported in subsequent safety updates [I have reviewed all early drop-outs in the 1986 safety updates (second and third)] who got into serious difficulty from the hypotension. That now represents 381 esmolol patients in the 04, 05, 07, 12/20/36, and 31 studies and, in the third safety update (which includes cases in the second safety update), another 72 + patients with SVT and other relevant diseases. There were two deaths in these studies each occurring well after esmolol (1 case) or propranolol (1 case) was discontinued. The esmolol patient had possible alcoholic cardiomyopathy and atrial fibrillation. She developed hypotension (causing esmolol to be stopped) although she had converted to NSR and had a persistent tachycardia of about 115 and a BP of about 100/60 after esmolol was stopped. Nine hours after discontinuation she developed intractable VT/VF. The investigator expressed great certainty that the drug played no role in the death or ventricular arrhythmia.

Many other patients with heart disease (not counting those in the surgery studies) also received esmolol, including 44 in hemodynamic and electrophysiology studies 13, 14, and 15, and about one hundred in various studies in unstable angina, CAD, or AMI.

The two patients who got into difficulty, one considerable difficulty, were not SVT patients but patients with significant CAD. One was a patient in Keefe's AMI study (Study 67, patient 1) with recent inferior MI, who developed sinus bradycardia, hypotension and sinus pauses of up to 7.5 sec. Before recovery (7 minutes after infusing esmolol) BP fell to 70 systolic (from 116/80) and HR to 35-40. It would be hard to tell what problem was primary but patients with inferior infarctions are susceptible to bradycardia, sinus arrest, etc., probably with any beta blocker. The 7 minute recovery time is probably shorter than would have been seen with other agents.

The second patient who developed severe problems was a patient in Wallis' unstable angina study (Study 69, patient 1) whose heart rate fell to 70, BP to 84/50 (had been 120/50-53) during infusion. The infusion was slowed, then stopped, but BP fell to 62/30, and HR gradually fell to 40, then 30, then 11, then 0. Atropine reversed all this, along with 15 seconds of CPP. It is again difficult to know what the primary agent was. It would seem BP was allowed to stay down too long but it was the HR effect, which is not a unique effect of esmolol, that was probably more important than the BP effect.

The hypotension thus seems to have been manageable and the short recovery time appears to be an advantage that can compensate for the excess hypotension. The alternative therapies, such as propranolol or verapamil can also cause excessive hypotension, even if less frequently, as the propranolol study and study 59 (esmolol vs verapamil) show. With regard to the latter study, not yet reported to us in full, the third safety update reports 4 hypotension (2 moderate, 2 mild) on esmolol vs 6 (3 moderate, 3 mild) on verapamil, among about 20 patients treated during the reporting period.

As you point out, any advantage/benefit of esmolol applies most clearly where treatment is expected to be short term, not where chronic therapy is planned. It would be tempting, of course, to consider esmolol a possible beta-blocker "test dose", but at this point it would seem potentially misleading, perhaps implying (by causing hypotension), intolerance to those agents where general intolerance is not truly present.

In sum, with proper labeling and patient selection, I agree with you and the Committee that esmolol should be approved for rapid control of ventricular rate in short-term circumstances.

NDA 10-386

Du Pont Critical Care Inc.
Attention: Kenneth G. Kesses, Ph.D.
1600 Waukegan Road
McGaw Park, IL 60085

Dear Dr. Kesses:

Please refer to your December 31, 1984 new drug application submitted under section 505(b)(1) of the Federal Food, Drug, and Cosmetic Act for Brevibloc (esmolol HCl) Injection.

We also acknowledge receipt of your October 31 and November 30, 1984 presubmissions of chemistry information and your amendments dated February 4, 8 and 27, March 13, May 2 and 14, July 22, August 2, 20, 26 and 29, October 7, November 3, 12, 20 and 26, 1985; January 17, March 5 and 24, April 22, May 3, September 11, 15 and 19, October 23, November 7, and December 8, 1986.

We have completed our review of this application as submitted with draft labeling and find the data submitted are sufficient to warrant approval of esmolol for short term control of ventricular rate in patients with atrial flutter/fibrillation.

Although the use of esmolol for this indication is approvable, the prominent hypotensive effect of esmolol requires explanation through postmarketing study. We suggest comparison of the hemodynamic effects of esmolol to those of propranolol, atenolol and metoprolol. Details of such a study can be discussed with the Division of Cardio-Penal Drug Products.

Before the application can be approved, however, it will be necessary for you to submit final printed labeling. The labeling should be essentially identical in content to the enclosed marked-up draft. In addition, please use the second chemical name listed in USAN (+)-Methyl p-[2-hydroxy-3-(isopropylamino)propoxy] hydrocinnamate hydrochloride to show that it is a racemate.

If additional information relating to the safety or effectiveness of this drug becomes available before we receive the final printed labeling, revision of that labeling may be required.

In addition, we would appreciate your submitting copies of the introductory promotional material that you propose to use for this product. Please submit one copy to the Division of Cardio-Renal Drug Products and a second, along with a copy of the package insert, directly to:

Division of Drug Advertising and Labeling, HFP-240
Room 108-04
5600 Fishers Lane
Rockville, Maryland 20857

Please submit all proposed materials in draft or mock-up form, not final print. Also, please do not use Form FD-2253 for this submission; this form is for routine use, not proposed materials.

Please submit twelve copies of the printed labels and other labeling seven of which are individually mounted on heavy weight paper or similar material.

Within 10 days after the date of this letter, you are required to amend the application, notify us of your intent to file an amendment, or follow one of your other options under 21 CFR 314.110. In the absence of such action FDA may take action to withdraw the application.

The drug may not be legally marketed until you have been notified in writing that the application is approved.

APPROVABLE

BREVIBLOC®
(esmolol hydrochloride)
INJECTION

10 mL Ampul - 2.5 g

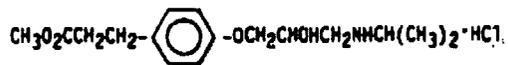

NOT FOR DIRECT INTRAVENOUS INJECTION. BREVIBLOC® MUST BE DILUTED PRIOR TO ITS INFUSION (SEE DOSAGE AND ADMINISTRATION SECTION).

DESCRIPTION

BREVIBLOC® (esmolol HCl) is a beta₁-selective (cardioselective) adrenergic receptor blocking agent with a very short duration of action (elimination half-life is approximately 9 minutes). Esmolol HCl is:

(±)-Methyl ~~p~~-(2-hydroxy-3-(isopropylamino) propoxy) phenyl ~~propionate~~ *hydrocinnamate* hydrochloride

and has the following structure:

Esmolol HCl has the empirical formula $C_{16}H_{26}NO_4Cl$ and a molecular weight of 331.8. It has one asymmetric center and exists as an enantiomeric pair.

Esmolol HCl is a white to off-white crystalline powder. It is a relatively hydrophilic compound which is very soluble in water and freely soluble in alcohol. Its partition coefficient (octanol/water) at pH 7.0 is 0.42 compared to 17.0 for propranolol.

BREVILOC® (esmolol HCl) INJECTION is a clear, colorless to light yellow, sterile, nonpyrogenic solution for intravenous infusion after dilution. It has a pH range of 3.5 to 5.5.

2.5 g, 10 mL Ampul - Each mL contains 250 mg esmolol HCl in 25% Propylene Glycol, USP, 25% Alcohol, USP and Water for Injection, USP, buffered with 17.0 mg Sodium Acetate, USP, and 0.00715 mL Glacial Acetic Acid, USP. Sodium hydroxide and/or hydrochloric acid added, as necessary, to adjust pH.

CLINICAL PHARMACOLOGY

Brevibloc® is a β_1 -selective (cardioselective) adrenergic receptor blocking agent with rapid onset, a very short duration of action, and no significant intrinsic sympathomimetic or membrane stabilizing activity at therapeutic dosages. Its elimination half-life after intravenous infusion is approximately 9 minutes. Brevibloc® inhibits

the beta₂ receptors located chiefly in cardiac muscle, but this preferential effect is not absolute, however, and at higher doses it begins to inhibit beta₂ receptors located chiefly in the bronchial and vascular musculature. ~~This Brevibloc preferentially inhibits the chronotropic and inotropic responses to beta-adrenergic stimulation.~~

Pharmacokinetics and Metabolism

Using an appropriate loading dose, steady-state blood levels of Brevibloc® for dosages from 50-300 mcg/kg/min are obtained within five minutes. ~~Blood levels of Brevibloc® increase linearly over this dosage range, and elimination kinetics are dose-independent over this range.~~ ~~Steady-state blood levels are maintained during infusion but decrease rapidly after termination of the infusion.~~ ~~The elimination half-life of Brevibloc® after intravenous infusion is approximately 9 minutes.~~ ~~Thus, because of its short half-life, blood levels of Brevibloc® can be rapidly altered by increasing or decreasing the infusion rate and rapidly eliminated by discontinuing the infusion.~~

~~Steady state is reached in about 30 minutes without the loading dose.~~ ~~Steady state~~
~~reflecting the distribution half-life initially.~~
~~rapidly by hydrolysis of the ester linkage,~~
Brevibloc® is metabolized chiefly by the esterases in the cytosol of red blood cells and not by plasma cholinesterases or red cell membrane acetylcholinesterase. Total body clearance in man was found to be about 20 L/kg/hr, ~~since this is~~ greater than cardiac output, the metabolism of Brevibloc® is not limited by the rate of blood flow to metabolizing tissues such as the liver, ~~or affected by hepatic or renal blood flow.~~ Brevibloc® has a rapid ~~and dose-independent~~ half-life of about 9 minutes. ~~Consistent with the high~~ rate of blood-based metabolism of Brevibloc®, less than 2% of the drug is excreted unchanged in the urine. Within 24 hours of the end of

infusion, approximately 73-88% of the dosage has been accounted for in the urine as the acid metabolite of Brevibloc®. ~~Elimination kinetics of Brevibloc® have been found to be independent of the dosage in the range of 50 to 300 mcg/kg/min.~~

Metabolism of Brevibloc® ^{results} ~~occurs via hydrolysis of the ester resulting~~ in the formation of the corresponding free acid and methanol. The ~~acid~~ ^{acid} metabolite ~~has been found to be independent of the dose while its elimination half-life is about 3.7 hours and it is excreted in the urine with a clearance equal to the glomerular filtration rate.~~ ^{is} Methanol blood levels, monitored in subjects receiving Brevibloc® for up to 6 hours at 300 mcg/kg/min and 24 hours at 150 mcg/kg/min, approximated endogenous levels and were less than 2% of levels usually associated with methanol toxicity. ~~The pharmacokinetics of Brevibloc® have also been evaluated in patients with hepatic disease (cirrhotic) and end-stage renal disease and were unchanged in these patients compared to those in normal subjects.~~

metabolite has been shown in animals to have about 1/1500th the activity of esmolol and in normal volunteers its blood levels do not correspond to the level of beta blockade.

^{Excretion} ~~The pharmacokinetics of the acid metabolite, however, were significantly different in patients with renal disease, with the elimination half-life in these patients was increased about ten times that of normals, and the plasma levels were considerably elevated.~~

Brevibloc® has been shown to be 55% bound to human plasma protein, while the acid metabolite is only 10% bound.

Pharmacodynamics

Clinical pharmacology studies in normal volunteers have confirmed the beta blocking activity of Brevibloc[®] showing reduction in heart rate at rest and during exercise, and attenuation of isoproterenol-induced increases in heart rate. Brevibloc blood levels have been shown to correlate with extent of beta blockade. After termination of infusion,

Substantial recovery from beta blockade is observed in 10-20 minutes

In human electrophysiology studies, Brevibloc[®] produced effects typical of a beta blocker: a decrease in the heart rate, increase in sinus cycle length, prolongation of the sinus node recovery time, prolongation of the AH interval during normal sinus rhythm and during atrial pacing, and an increase in antegrade Wenckebach cycle length.

undergoing radioactive angiography,

In patients, Brevibloc[®], at dosages of 200 mcg/kg/min, produced reductions in heart rate, ^{systemic blood pressure} rate pressure product, left and right ventricular ejection fraction and cardiac index ^{of rest} which were similar in magnitude to those produced by intravenous propranolol (4 mg). During exercise, Brevibloc[®] produced reductions in heart rate, rate pressure product and cardiac index which were also similar to those produced by propranolol,

but produced a significantly larger fall in ^{systemic blood pressure} systolic blood pressure. In patients undergoing cardiac catheterization, the maximum therapeutic dose of 300 mcg/kg/min of Brevibloc[®] produced ^{similar effects, and, in addition, there was} ~~decreases in the heart rate, systolic blood pressure, rate pressure product, left ventricular ejection fraction, and cardiac index~~ and small, clinically insignificant increases in the left ventricular end diastolic pressure and pulmonary capillary wedge pressure. At thirty minutes after the discontinuation of Brevibloc[®] infusion, all of the hemodynamic parameters had returned to pretreatment levels.

10 The relative cardioselectivity of Brevibloc® was demonstrated in mildly asthmatic patients and in patients with chronic obstructive pulmonary disease (COPD). In mildly asthmatic patients, Brevibloc® infusions (100, 200 and 300 mcg/kg/min) produced no significant increases in specific airway resistance when compared to placebo. At 300 mcg/kg/min, Brevibloc® produced slightly enhanced bronchomotor sensitivity to dry air stimulus. These effects were not clinically significant, and Brevibloc® was well tolerated by these patients. No patients were discontinued from the study. Six of these patients also received intravenous propranolol, and at a dosage of 1 mg, two experienced significant, symptomatic bronchospasm requiring bronchodilator treatment. One other propranolol-treated patient also experienced dry air-induced bronchospasm. No adverse pulmonary effects were observed in patients with COPD who received therapeutic dosages of Brevibloc® for treatment of supraventricular tachycardia (51 patients) or in perioperative settings (32 patients).

~~In a study in patients with elevated heart rates and acute ischemic heart disease (unstable angina pectoris or acute myocardial infarction), Brevibloc®, when titrated from 50 to 300 mcg/kg/min lowered heart rate and blood pressure; and had no significant effect on left ventricular filling pressure or systemic vascular resistance, but decreased cardiac index. Cardiac index returned to pretreatment levels within 30 minutes after discontinuation of the infusion.~~

~~Following loading and maintenance infusions of Brevibloc®, blood levels and beta blockade are at steady state within 5 minutes. If a loading dosage is not used, approximately 30 minutes is required to reach steady state blood levels. Brevibloc® blood levels have also~~

moved

~~been correlated with levels of beta-blockade. After termination of Brevibloc infusions, substantial recovery from beta-blockade has been observed within 10 to 20 minutes.~~

~~The sole metabolite of Brevibloc[®] has been shown in animals to have 1/1580th the beta-blocking potency of Brevibloc[®]. In normal volunteers no correlations have been observed between the blood levels of this metabolite and beta blockade following the administration of Brevibloc[®].~~

mouse

Supraventricular Tachycardia

~~In a randomized, double-blind, placebo-controlled, multicenter study of Brevibloc[®] in maintenance dosages of 50 to 300 mcg/kg/min, was found to be more effective than placebo in the treatment of supraventricular tachycardia, ~~including~~ atrial flutter, atrial fibrillation, and sinus tachycardia. Sixty-four (64) percent of the Brevibloc-treated patients had a desired therapeutic effect (either a 20% reduction in heart rate, a decrease in heart rate to less than 100 bpm, or, rarely, conversion to NSR) and 55% of these responses did so at a dosage of 200 mcg/kg/min or less. The average effective dosage of Brevibloc[®] was approximately 100 mcg/kg/min in the two studies. Other multicenter baseline-controlled studies gave essentially similar results.~~

and about as effective as propranolol, given as 3-6 mg by bolus injection,

~~In another randomized, double-blind, multicenter study in which patients with supraventricular tachycardia received either Brevibloc[®] or propranolol, Brevibloc[®] in dosages of 50 to 300 mcg/kg/min was found to be comparable in efficacy to propranolol, 3 to 6 mg given by intravenous bolus injection. Seventy-two (72) percent of the~~

results. In the comparison with propranolol, about 50% of patients in the Brevibloc and propranolol groups were on concomitant digoxin. Response rates were slightly higher with both beta-blockers in the digoxin-treated patients.

~~87% of the propranolol-treated patients achieved a therapeutic response, and 97% of the patients who responded to Brevibloc® had a therapeutic response at doses of 200 mcg/kg/min or less. The average effective dosage of Brevibloc® in this study was approximately 115 mcg/kg/min.~~

In a large, base line-controlled study, Brevibloc® was infused at dosages of 25 to 300 mcg/kg/min for periods up to 24 hours. The effective dosage that produced either a 15% reduction in the heart rate or a conversion to NSR ranged from 25 to 200 mcg/kg/min with 79% of patients responding, and 95% of the responders did so at 200 mcg/kg/min or less. In another multicenter trial, patients controlled on Brevibloc® were transferred to one of several oral or intravenous antiarrhythmic agents for chronic treatment of supraventricular tachycardia. (See Dosage and Administration.)

In all studies, significant decreases of blood press

Perioperative Tachycardia and Hypertension

~~In three multicenter, randomized, double-blind, placebo-controlled studies, Brevibloc® (500 mcg/kg/min for 4 minutes followed by 300 mcg/kg/min) was found to be effective in inhibiting the increases in heart rate, systolic and mean arterial blood pressures, and rate-pressure product following endotracheal intubation. Brevibloc® reduced the incidence of clinically significant increases in heart rate (≥ 100 bpm) and systolic blood pressure (> 180 mmHg) following intubation when compared to placebo. Brevibloc® was well tolerated without significant adverse effects.~~

occurred in 20-50% of patients, identified either as adverse reaction reports by investigators or by observation of systolic pressure less than 90 mmHg or diastolic pressure less than 50 mmHg. The hypotension was symptomatic in about 12% of patients and led to discontinuation of therapy in about 11%. In comparison to propranolol, hypotension was about three times as frequent with esmolol, 53% vs 17%. The hypotension was rapidly reversible with decreased infusion rate or discontinuation of esmolol therapy. For both esmolol and propranolol hypotension was reported less frequently in patients receiving concurrent digoxin

~~In a fourth multicenter, randomized, double-blind, placebo-controlled trial in patients undergoing coronary artery bypass grafting, Brevibloc® (500 mcg/kg/min for 2 minutes followed by 200 mcg/kg/min was found to be effective in reducing the tachycardia and hypertension and the increase in rate pressure product associated with various stimuli occurring between the period prior to induction of anesthesia and the start of cardiopulmonary bypass surgery. In addition, the patients receiving Brevibloc® also required significantly less supplemental inhalation anesthetic and less pharmacological intervention to maintain heart rate or arterial blood pressure. When compared to placebo, Brevibloc® reduced the incidence of clinically significant increases in heart rate (≥ 100 bpm) and systolic blood pressure (≥ 100 mmHg). Brevibloc® was well tolerated in this study.~~

INDICATIONS AND USAGE

Supraventricular Tachycardia

Brevibloc® is indicated for the rapid control of ventricular rate in ~~patients with~~ atrial fibrillation ^{or} atrial flutter, ~~and concomitantly or~~ ^{post-operative} ~~catecholamine-induced sinus tachycardia~~ in perioperative, or other ^{circumstances} emergent situations where ~~rapid~~ ^{short-term} control of ventricular rate ~~is desired.~~ ^{with a short-acting agent is desirable.} Brevibloc is not intended for use in chronic settings where transfer to another agent is anticipated. ~~that may be withdrawn rapidly. Examples would include patients with~~ ~~minimal degrees of ventricular dysfunction, or with possible disorders~~ of the cardiac pacemaker or conduction system. (See Precautions.)

CONTRAINDICATIONS

Brevibloc® is contraindicated in patients with sinus bradycardia, heart block greater than first degree, cardiogenic shock and overt heart failure (see WARNINGS).

WARNINGS

Hypotension:

Cardiac Failure: Continued depression of the myocardium with beta blocking agents over a period of time can, in some cases, lead to cardiac failure. At the first sign or symptom of impending cardiac failure, the dosage should be reduced or Brevibloc® should be withdrawn. Although this dosage adjustment or withdrawal may be sufficient because of the short elimination half-life of Brevibloc®, specific treatment may also be considered. (See Overdosage.)

10

Sympathetic stimulation is necessary in supporting circulatory function in congestive heart failure, and beta blockade carries the potential hazard of further depressing myocardial contractility and precipitating more severe failure.

In clinical trials, 20-50% of patients treated with Brevibloc have had hypotension, generally defined as a systolic pressure of less than 90 mmHg and/or a diastolic pressure of less than 50 mmHg. This does not appear to be related solely to beta-blockade, as propranolol at similar beta-blocking doses, caused hypotension about one-third as often. About 12% of hypotensive patients have been symptomatic. Hypotension can occur at any dose but is dose-related so that doses beyond 200 mcg/kg/minute are not recommended. Patients should be closely monitored, especially if pretreatment blood pressure is low. Discontinuation of dose or termination of Brevibloc infusion reverses hypotension, usually within 30 minutes.

Bronchospastic Diseases: PATIENTS WITH BRONCHOSPASTIC DISEASES SHOULD, IN GENERAL, NOT RECEIVE BETA BLOCKERS. Because of its relative beta₁ selectivity and titratability, Brevibloc® may be used with caution in patients with bronchospastic diseases. However, since beta₁ selectivity is not absolute, Brevibloc® should be carefully titrated to obtain the lowest possible effective dose. In the event of bronchospasm, the infusion should be terminated immediately and a beta₂ stimulating agent may be administered if conditions warrant.

with particular caution as patients already have rapid ventricular rates.

Diabetes Mellitus and Hypoglycemia: Brevibloc® should be used with caution in diabetic patients requiring a beta-blocking agent. Beta blockers may mask tachycardia occurring with hypoglycemia, but other manifestations such as dizziness and sweating may not be significantly affected.

~~Brevibloc® has been given to a limited number of patients with mild manifestations of the above three conditions without exacerbation of the respective existing condition. This experience includes 45 patients with mild CHF, 42 patients with mild COPD and 37 patients with diabetes mellitus.~~

PRECAUTIONS

General

~~In patients with supraventricular tachycardia, Brevibloc has been shown to produce a decrease in systolic blood pressure. Accordingly, patients with low pretreatment systolic pressures should be carefully observed during titration and maintenance infusions with Brevibloc.~~

Included in warnings

Infusion concentrations of 20 mg/mL ~~have been~~ ^{were} associated with ~~significant~~ ^{more} venous irritation and thrombophlebitis ~~in patients~~ ^{than were} concentrations of 10 mg/mL. ~~Therefore,~~ Concentrations greater than 10 mg/mL should be avoided.

Because the acid metabolite of Brevibloc® is primarily excreted unchanged by the kidney, Brevibloc® should be administered with caution to patients with impaired renal function. The elimination half-life of the acid metabolite was prolonged ten-fold and the plasma level was considerably elevated in patients with end-stage renal disease.

Drug Interactions

Catecholamine-depleting drugs, e.g., reserpine, may have an additive effect when given with beta blocking agents. Patients treated concurrently with Brevibloc® and a catecholamine depletor should therefore be closely observed for evidence of hypotension or marked bradycardia, which may result in vertigo, syncope, or postural hypotension.

~~From~~ ^{As} the interaction study between Brevibloc® and warfarin showed that concomitant administration of Brevibloc and warfarin does not alter warfarin plasma levels. Brevibloc® concentrations ~~were~~ were equivocally higher when given with warfarin, *but this is not likely to be clinically important.*

When digoxin and Brevibloc® were concomitantly administered intravenously to normal volunteers, there was a 10-20% increase in digoxin blood levels at some time points. Digoxin did not affect Brevibloc® pharmacokinetics. When intravenous morphine and Brevibloc® *were consistently administered* ~~interaction was studied~~ in normal subjects, no effect on morphine blood levels was seen, *but* ~~the~~ Brevibloc® steady-state blood levels were increased by 46% in the presence of morphine, ~~but~~ *no* other pharmacokinetic parameters were changed.

The effect of Brevibloc® on the duration of succinylcholine-induced neuromuscular blockade was studied in patients undergoing surgery. The onset of neuromuscular blockade by succinylcholine was unaffected by Brevibloc®, but the duration of neuromuscular blockade was prolonged from 5 minutes to 8 minutes.

Although the interactions observed in these studies *do appear to be* ~~are not~~ of major clinical importance, Brevibloc® should be titrated with caution in patients being treated concurrently with digoxin, morphine, succinylcholine or warfarin.

~~The hypotensive effects of inhalation anesthetic agents may be increased in the presence of Brevibloc®. The dosage of either agent may be modified as needed to maintain the desired hemodynamics.~~

Carcinogenesis, Mutagenesis, Impairment of Fertility

Because of its short term usage no carcinogenicity, mutagenicity or reproductive performance studies have been conducted with Brevibloc®.

Pregnancy Category C

Teratogenicity studies in rats at intravenous dosages of Brevibloc® hydrochloride up to 3000 mcg/kg/min (ten times the maximum recommended human maintenance dosage) for 30 minutes daily produced no evidence of maternal toxicity, embryotoxicity or teratogenicity, while a dosage of 10,000 mcg/kg/min produced maternal toxicity and lethality. In rabbits, intravenous dosages up to 1000 mcg/kg/min for 30 minutes daily produced no evidence of maternal toxicity, embryotoxicity or teratogenicity, while 2500 mcg/kg/min produced minimal maternal toxicity and increased fetal resorptions.

There are no adequate and well controlled studies in pregnant women. Brevibloc® should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Nursing Mothers

It is not known whether Brevibloc® is excreted in human milk, however, caution should be exercised when Brevibloc® is administered to a nursing woman.

Pediatric Use

The safety and effectiveness of Brevibloc® in children ^{have} not been established.

ADVERSE REACTIONS

Supraventricular Tachycardia

The following adverse reaction rates are based on use of Brevibloc® in almost 400 clinical trial patients with supraventricular tachycardia. ~~has been studied in 269~~ In addition, a total of ~~patients~~ ^{patients} have been exposed in clinical studies of other conditions. Most adverse effects have been mild and transient.

The most common and important adverse effect has been hypotension (see warnings)

Cardiovascular - symptomatic hypotension (diaphoresis, dizziness) occurred in 12% of patients and required discontinuation of therapy in ^{about 11%} ~~about 11%~~. Asymptomatic hypotension occurred in ^{about} 25% of patients. Hypotension resolved during the Brevibloc® infusion in 63% of these patients and within 30 minutes after discontinuation of infusion in 80% of the remaining patients. Diaphoresis ^{accompanied hypotension and} occurred in 10% of patients. Peripheral ischemia occurred in approximately 1% of patients. Pallor, flushing, bradycardia (heart rate less than 50 beats per minute), chest pain, syncope, pulmonary edema and heart block have each been reported in less than 1% of patients.

In two patients without supraventricular tachycardia but with serious coronary artery disease (post inferior myocardial infarction or unstable angina) severe bradycardia / sinus pause / asystole has developed, reversible in both cases with discontinuation of treatment.

Central Nervous System - Dizziness has occurred in 3% of patients; somnolence in 3%, confusion, headache, and agitation in about 2%, and fatigue in about 1% of patients. Paresthesia, asthenia, depression, abnormal thinking, anxiety, anorexia, and lightheadedness were reported in less than 1% of patients. One brief (30 second) episode of grand mal seizure has been reported.

Respiratory - bronchospasm, wheezing, dyspnea, nasal congestion, rhonchi, and rales have each been reported in less than 1% of patients.

Gastrointestinal - nausea was reported in 7% of patients. Vomiting has occurred in about 1% of patients. Dyspepsia, constipation, dry mouth, and abdominal discomfort have each occurred in less than 1% of patients. *Taste perversion has also been reported*

Skin (Infusion Site) - Infusion site reactions including inflammation and induration were reported in about 8% of patients. Edema, erythema, skin discoloration, and burning at the infusion site have each occurred in less than 1% of patients.

Miscellaneous - each of the following has been reported in less than 1% of patients: Urinary retention, speech disorder, abnormal vision, midscapular pain, rigors, and fever.

~~Perioperative tachycardia and hypertension~~

~~Of the patients treated with Brevibloc in operative settings (N=296), very few adverse effects have been reported. The most commonly observed adverse effect was mild hypotension in 4% of patients. The other reported adverse effect was bradycardia (heart rate less than 50 bpm), which occurred in less than 1% of patients. None of these adverse effects was severe, and all resolved soon after discontinuation of Brevibloc.~~

OVERDOSAGE

Acute Toxicity

A single case of accidental overdosage with Brevibloc® has occurred to date. A 5000 mcg/kg/min dose of Brevibloc® instead of the recommended 500 mcg/kg/min loading dose, was administered over one minute to a patient with atrial flutter. Immediately following the infusion, marked decreases in heart rate and blood pressure were observed and the patient became drowsy but could be aroused. The infusion rate of Brevibloc® was decreased to 5 mcg/kg/min and over the next eight minutes the patient's rhythm converted to normal sinus rhythm and the patient started feeling better. Hypotension persisted for a period of four minutes after decreasing the dosage of Brevibloc®. The drowsiness disappeared 15 minutes following discontinuation of Brevibloc®.

Because of its approximately 9-minute elimination half-life, the first step in the event of toxicity should be to discontinue Brevibloc® administration. Then, based on the pharmacologic actions, the following general measures should also be considered:

Bradycardia: Intravenous administration of atropine or another anticholinergic drug.

Bronchospasm: Intravenous administration of a beta₂ stimulating agent and/or a theophylline derivative.

Cardiac Failure: Intravenous administration of a diuretic and/or digitalis glycoside. In shock resulting from inadequate cardiac contractility, intravenous administration of dopamine, dobutamine, isoproterenol, or amrinone may be considered.

DOSAGE AND ADMINISTRATION

NOT FOR DIRECT INTRAVENOUS INJECTION. BREVIBLOC® IS A CONCENTRATED, POTENT DRUG WHICH MUST BE DILUTED PRIOR TO ITS INFUSION. BREVIBLOC® SHOULD NOT BE ADMIXED WITH SODIUM BICARBONATE. BREVIBLOC® SHOULD NOT BE MIXED WITH OTHER DRUGS PRIOR TO DILUTION IN A SUITABLE INTRAVENOUS FLUID. (See Compatibility Section below.)

Note: Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration, whenever solution and containers permit.

Dilution: Aseptically remove 20 mL from a 500-mL bottle of one of the intravenous fluids listed below (see Compatibility with Commonly Used Intravenous Fluids), and add the contents of two (2) Brevibloc® ampuls (each containing 2.5 g esmolol hydrochloride). This yields a final concentration of 10 mg/mL. The diluted solution is stable for at least 24 hours at room temperature. Note: Brevibloc® concentrations of greater than 10 mg/ml are likely to produce irritation on continued infusion [See Precautions]. Brevibloc® has, however, been well tolerated when administered via a central vein.

Supraventricular Tachycardia

In the treatment of supraventricular tachycardia, Brevibloc® usually *response to (over 95%)* occurs effective within ~~the~~ *the* range of 50 to 200 mcg/kg/min. The average effective dosage is approximately 100 mcg/kg/min, although dosages as *low as 25 mcg/kg/min have been used (but adequate response not seen).* high as 300 mcg/kg/min have been used, *but these provide little added effect and an increased risk of adverse effects and are not recommended.* ~~in some patients, a dosage of 25 mcg/kg/min has been adequate. For this reason, Brevibloc® dosage in supraventricular tachycardia must be individualized by titration in which each step consists of a loading dosage followed by a maintenance dosage.~~

To initiate treatment of a patient with supraventricular tachycardia, administer a loading dosage infusion of 500 mcg/kg/min of Brevibloc® for one minute followed by a 4 min. maintenance infusion of 50 mcg/kg/min. If an adequate therapeutic effect is not observed within five minutes, repeat the same loading dosage and follow with a maintenance infusion increased to 100 mcg/kg/min.

Continue titration procedure as above, repeating loading infusion (500 mcg/kg/min for 1 minute), increasing maintenance infusion by increments of 50 mcg/kg/min (for 4 minutes). As the desired heart rate or a safety end-point (e.g., lowered blood pressure) is approached, omit loading infusion and reduce incremental dose in maintenance infusion from 50 mcg/kg/min to 25 mcg/kg/min or lower. Also, if desired, increase interval between titration steps from 5 to 10 minutes.

Maintenance dosages above 200 mcg/kg/min have not been shown to have significantly increased benefits, and the ~~effectiveness~~^{safety} of dosages above 300 mcg/kg/min has not been studied.

In the event of an adverse reaction, the dosage of Brevibloc® may be reduced or discontinued. If a local infusion site reaction develops, an alternative infusion site should be used. The use of butterfly needles should be avoided.

Abrupt cessation of Brevibloc® in patients has not been reported to produce the withdrawal effects which may occur with abrupt withdrawal of beta-blockers following chronic use in coronary artery disease (CAD) patients. However, caution should still be used in discontinuing Brevibloc® infusions abruptly in CAD patients.

After achieving an adequate control of the heart rate and a stable-clinical status in patients with supraventricular tachycardia, transition to alternative antiarrhythmic agents such as propranolol, digoxin, or verapamil, may be accomplished. A recommended guideline for such a transition is given below but the physician should carefully

consider the labeling instructions for the alternative agent selected:

<u>Alternative Agent</u>	<u>Dosage</u>
Propranolol hydrochloride	10-20 mg q 4-6 h
Digoxin	0.125 - 0.5 mg q 6 h (p.o. or i.v.)
Verapamil	80 mg q 6 h

The dosage of Brevibloc® should be reduced as follows:

1. Thirty minutes following the first dose of the alternative agent, reduce the Brevibloc® infusion rate by one-half (50%).
2. Following the second dose of the alternative agent, monitor the patient's response and if satisfactory control is maintained for the first hour, discontinue the Brevibloc® infusion.

The use of Brevibloc® infusions up to 24 hours has been well documented; in addition, limited data from 24-48 hrs (N=48) indicate that Brevibloc® is well tolerated up to 48 hours.

~~Perioperative Tachycardia and Hypertension~~

~~In these perioperative settings where it is not possible to convert Brevibloc® to the desired therapeutic effect, such as induction, intubation and surgical manipulations, to obtain a rapid~~

~~onset, Brevibloc® should be infused in a loading dosage of 300 mcg/kg/min for four minutes followed by a maintenance dosage of 300 mcg/kg/min. If a lower dose is desired, for example, in the presence of high-dose narcotic anesthesia, the loading dosage of 500 mcg/kg/min may be reduced to 2 minutes and the maintenance dosage to 200 mcg/kg/min. If necessary, the dosage may be subsequently reduced.~~

~~The hypotensive effects of inhalation anesthetic agents may be increased in the presence of Brevibloc®. The dosage of either agent may be modified as needed to maintain the desired hemodynamics.~~

Compatibility with Commonly Used Intravenous Fluids

BREVIBLOC® (esmolol HCl) INJECTION was tested for compatibility with eight commonly used intravenous fluids at a final concentration of 10 mg esmolol HCl per mL. BREVIBLOC® INJECTION was found to be compatible with the following solutions and was stable for at least 24 hours at controlled room temperature or under refrigeration:

- Dextrose (5%) Injection, USP
- Dextrose (5%) in Ringer's Injection
- Dextrose (5%) and Sodium Chloride (0.45%) Injection, USP
