I. Glossary

Amenorrhea – No menstrual bleeding, not even one drop.

Anesthesia – Medical treatment with drugs to reduce and/or stop pain.

Cervix – Part of the uterus that contains the cervical canal and connects the uterus to the vagina.

Clinical Study – A carefully planned test in people to find out if a new medical product or treatment is safe and if it works.

Diagnostic – A test or procedure to identify a disease or problem.

Dilation and Curettage (also called a D & C) – A surgical procedure your doctor uses to go through your vagina to gently scrape and remove the lining of the uterus (endometrium).

Dysfunction – The change of a body or organ function from normal to not normal. Another word for dysfunction is abnormal.

Endometrial Ablation – A surgical treatment to eliminate the endometrium, the tissue lining of the uterus, and the source of excessive menstrual bleeding.

Effectiveness – The measure of how well a medical treatment works.

Endometrium – The tissue lining of the uterus and the source of excessive menstrual bleeding.

Estrogen – A chemical substance made by your body. Estrogen plays a very important role in your menstrual cycle, becoming pregnant, and many other body functions.

FDA – The United States Food and Drug Administration is the government agency whose mission is to protect and promote public health by protecting the safety of the food supply and giving the public access to safe and effective medical products.

Gynecologist – A doctor who specializes in treating the female reproductive system.

Hormone – A chemical made in your body. Your body makes hundreds of hormones and uses hormones to control a large number of body functions.

Hysterectomy – A surgical procedure to remove the uterus.

Hysteroscopy – Procedure completed using a hysteroscope, a thin, lighted tube with a camera that is inserted into the vagina to examine the cervix and inside of the uterus.

IUD – Intra-Uterine Device. A birth control device prescribed by your doctor to prevent pregnancy. Your doctor places the small device inside the uterus to prevent pregnancy.

Menopause – The natural biological process of gradually ending your monthly period (menstruation). Menopause also ends fertility. The average age of menopause is 51 years old in the United States. Women having menopause can have physical symptoms such as hot flashes, and emotional symptoms of menopause that may disrupt sleep, lower energy, or make them feel anxious or sad.

Minerva Controller – The computer and electronic part of the Minerva System that makes the device work.
Minerva Handpiece – The handheld part of the Minerva device that is used by physicians to treat the uterus.

Minimally Invasive Procedure – A procedure that can be done through the body's natural openings or through one or more small incisions to avoid large incisions (cuts).

Progestin – A hormone made by your body. Progestin has a very important role in your menstrual cycle, becoming pregnant, and many other body functions.

Success Rate – The percent (%) of patients who are expected to have their excessive bleeding reduced to a normal level or less than normal levels after endometrial ablation treatment.

Tubal Ligation – A surgical method of permanent birth control that closes a woman’s Fallopian tubes.

Ultrasound – Images of internal organs, like the uterus, that are made by a machine using sound waves.

II. What is the Minerva Endometrial Ablation System?

Minerva and You

If heavy periods are making it difficult for you to live a normal life, Minerva may have the answer for you. The Minerva treatment is a one-time, safe, effective, quick, and complete procedure that can reduce heavy bleeding. The treatment can be done at the hospital or at the doctor’s office or clinic without making incisions or using general anesthesia that puts you to sleep.

What is Heavy or Excessive Menstrual Bleeding?

A period with bleeding totaling over 1/3 cup (80ml) is considered heavy or excessive. If you have to change your sanitary protection (pads or tampons) frequently, (for example more than twice an hour,) excessive menstrual bleeding may be the cause. You may also feel weak, tired, and have no energy. Many women also say that excessive menstrual bleeding makes it difficult to work, exercise, and to be socially and sexually active.

This is a very common problem that affects about 1 in 5 women. The signs of heavy bleeding are most likely to start between the ages of 30 and 40.

How Does the Minerva System Work?

The Minerva System works by destroying the endometrium (lining of the uterus) with heat. This tissue is the source of heavy bleeding in women who have not reached menopause. Minerva is only for women who do not want to have children in the future.

Minerva System Description

The Minerva System has two main parts. The first is the Minerva Handpiece that your doctor inserts through your vagina into your uterus. The second part is the Minerva Controller that produces heat energy to treat the lining of your uterus. This energy is created by heating up argon gas that circulates inside of the Minerva Handpiece.
Minerva Endometrial Ablation System

The whole procedure time from insertion of the Minerva Handpiece to removal of the Minerva Handpiece is about 3 to 4 minutes.

Minerva Handpiece Placement Inside the Uterus
III. Who Cannot Have This Done?

The Minerva System should not be used in patients who have, or had, the following conditions:

- Currently pregnant or wants to become pregnant in the future. PREGNANCY AFTER ABLATION CAN BE DANGEROUS FOR BOTH MOTHER AND UNBORN BABY.
- Known or suspected cancer of the uterus.
- Any weakness of the wall of the uterus. This may be due to past surgeries or long-term use of some medications. Talk to your doctor for more information.
- Had an endometrial ablation in the past. Repeat ablation can cause serious injury.
- Current infection, for example of the uterus, ovaries, bladder or other organs. This procedure should be not be used if you have an infection. Any infection must heal before the ablation procedure can be scheduled.
- Intrauterine device (IUD) in the uterus. Patient must agree to remove the IUD before the treatment.
- Patients with Essure. It is not known whether the Minerva procedure is safe and effective in patients with the Essure procedure.
- A patient with a very small uterus should not have the treatment because it may result in injury. Your doctor will measure your uterus to see if it is too short or too narrow for the Minerva procedure.

IV. What are the Risks of the Minerva Treatment?

With any surgery, there are risks related to the treatment and to the anesthesia used during the treatment. Your doctor will talk to you about the risks of the Minerva treatment and will give you details about your individual situation. It is important for you to know the risks of the Minerva treatment.

The Minerva Endometrial Ablation System was tested in two clinical studies, the Minerva Single-Arm Study with 110 patients (study complete) and the Minerva Randomized Study with 102 patients (study in progress). Please see section XI for an explanation of how the two studies were done.

A number of risks were seen during this testing of the Minerva System. These risks are listed in the following table and were reported within the first month following the Minerva treatment. It is also important to know how often these risks may happen. In the table this information is shown using percent (%). The percent (%) shows how many patients had this event when 100 women were treated. For example, the 1% next to “fever” means that when 100 patients were treated, 1 patient experienced a fever. You can discuss these risks with your doctor for more information.

### Risks of the Minerva Treatment

The risks listed in the table below were reported within the first month following the Minerva treatment in the 212 women evaluated in the two clinical studies.

*** Ten patients in the Single-Arm Study and two patients in the RCT reported the same AE at the 24 hours – 2 Weeks and the >2 Weeks visits
† SAE (PID) occurred in one Minerva subject at 34 days

### Additional Risk-Related Information

The Minerva treatment is a surgical procedure. As with all surgeries, serious injury or death can occur. The following are also possible risks during or after endometrial ablation treatment.

1. Injury (e.g. tear) of the uterus.
2. Injury to organs in the abdomen (e.g., bowel or bladder).
3. Potential complication (e.g., new pain during menstrual cycles) in women who have previously had a tubal ligation.
4. Serious pregnancy complications for both mother and unborn baby. The Minerva procedure does not protect women from future pregnancy. Patients will still need to use contraception or undergo a permanent sterilization procedure.

5. Life-threatening infection. Patients should contact their doctor if they develop any of the following:
   a. Fever higher than 100.4 °F
   b. Abdominal pain that becomes worse and does not get better by pain medication given by the doctor or by ibuprofen
   c. Nausea
   d. Vomiting
   e. Bowel or bladder problems
   f. Vaginal discharge that has a foul smell.

6. Other risks and complications leading to serious injury or death. Undergoing an endometrial ablation procedure may make it more difficult to diagnose endometrial cancer in the future.

V. Benefits of the Minerva Treatment

The Minerva Treatment can be done at any time during the menstrual cycle. It is a 3 to 4 minute treatment that can be done in a clinic, and you do not need general anesthesia. Clinical studies tested the Minerva device and found that at one year after the Minerva treatment the following benefits were seen:

- 92 of 100 patients had their heavy bleeding reduced to a normal level or less.
- 66 out of 100 patients had no bleeding.
- Over half of the patients with menstrual cramping said that it decreased after the Minerva procedure.
- Patients had an improvement in sexual satisfaction.
- Patients had more energy to perform work and other activities outside their home.
- 98 out of 100 of the patients were satisfied with the results.

VI. How to Decide if the Minerva Treatment is Right for You?

The first step is to talk to your doctor about your heavy bleeding problem. Your doctor will do a series of tests to find the cause of your excessive menstrual bleeding. Excessive bleeding by itself is not a disease. It is a sign or symptom of a number of possible medical conditions.

Using ultrasound and/or hysteroscopy (methods used by doctors to look at the inside and outside of your uterus), and some other medical tests, your doctor will find the cause of your bleeding.

Your doctor will then help you select the right treatment. Depending on the reason for your excessive bleeding, your doctor may suggest that you first try medications. If medications do not work, or you are not allowed to take them for other medical reasons, your doctor may suggest endometrial ablation using the Minerva device.

The following table shows common treatments used for excessive bleeding and the advantages and disadvantages for each.
# Treatments for Excessive Bleeding

<table>
<thead>
<tr>
<th>Technology Description</th>
<th>Endometrial Ablation</th>
<th>Intrauterine (IUD) Hormone Releasing</th>
<th>Hormone Therapy</th>

</tbody>
</table>
It is very important for you to understand that **treatment with the Minerva Endometrial Ablation Device should only be performed if you are absolutely sure that you do not want to have children in the future.** This treatment cannot be undone or reversed. Becoming pregnant after this procedure is dangerous for both mother and unborn child. Your doctor will talk to you about ways to avoid pregnancy after surgery (birth control).

### VII. What Happens Before Treatment?

Before treatment, you will be taken to the treatment room. The nurse will take your blood pressure, temperature, and other important information. Nurses will likely tape a number of wires on your chest to keep track of how well your heart is working.

You will also be given some medication to help you with any pain and make you relax. An oxygen mask may also be placed on your face to help you breathe. Your doctor’s assistant will prepare you for the procedure by cleaning your vagina with a special solution that kills germs.

### VIII. What Happens During Treatment?

At the time of the procedure, the doctor will insert a speculum (a medical tool that opens your vagina) so that your doctor can see inside. The doctor may make your cervix numb so that you do not feel pain during the procedure. Based on this procedure, the doctor may determine that you are not a candidate for treatment with Minerva. In that case, the doctor will talk to you about other options to treat your heavy menstrual bleeding.

The doctor will turn on the Minerva Controller, and then gently dilate (open) your cervix to insert the soft tip of the Minerva device into your uterus. The Minerva Controller will then provide energy to heat the inside of your uterus for 2 minutes. At the end of the treatment, the doctor will remove the device from your uterus. The entire treatment, from the time the device is inserted until the device is removed, usually takes less than 4 minutes. No part of the Minerva device remains in the uterus after the treatment.
IX. What Happens After Treatment?

After treatment, you will be taken to a recovery area where you will be watched for about 1 hour to make sure you are okay. You may experience some mild to moderate low abdominal cramping and pain. The recovery room nurse may give you some medication for this. You will then be released to go home. It is important that someone is with you to take you home. You cannot drive immediately after the procedure because of the drugs you were given.

Most patients experience some mild low abdominal pain for a day or so, which usually is treated with over the counter (non-prescription) pain medication that your doctor will recommend. Patients also reported vaginal discharge following the procedure. During the first few days, the discharge is likely to be bloody in color, but it will gradually turn clear. The total time of vaginal discharge is expected to last for two to four weeks, so you will need to wear some sanitary protection (for example a panty liner) during this time.

X. When to Call Your Doctor?

Your doctor’s office will likely call you to check on you after your treatment. However, if after the procedure you are experiencing increasing pain, increased bleeding, change to greenish vaginal discharge, or have a fever greater than 100.4°F, immediately call your doctor’s office. In rare cases, endometrial ablation can cause a serious injury that, if not treated promptly, can lead to death. If you call your doctor at night or on a weekend, your doctor’s office will likely have an answering service that will put you in touch with your doctor or the doctor on-call. If you are not able to talk to your doctor, call 911 or go to the nearest Emergency Room.

XI. How Were the Clinical Studies Done?

The Minerva Endometrial Ablation System was tested in two clinical studies, the Minerva Single-Arm Study and the Minerva Randomized Study. Doctors who did these clinical studies were gynecologists and treated women with heavy bleeding. The women treated with the Minerva System were from 25 to 50 years old, had heavy monthly bleeding, and did not want to have more children. All of the women were examined to see if there was a cause of their excessive menstrual bleeding and to make sure they were healthy with no infection.

The Minerva Single-Arm study was done by seven doctors at different hospitals and clinics. There were 110 women included in this study. The women kept a record of their bleeding using special diary charts. They filled out the diaries for their periods before the Minerva treatment and then completed one diary for each monthly period after the Minerva treatment. Each diary was collected and the amount of bleeding each patient had before and after the Minerva treatment was determined. In order to be in the clinical study, the patient’s bleeding level had to be more than a certain amount. The Minerva treatment was considered successful if a patient had a bleeding level that was normal or below normal at 12 months following the Minerva treatment.
The women had follow-up visits with their doctor at 3 months, 6 months, and 1 year following the Minerva procedure. During these visits, the doctor examined the patients and collected their diaries to check their monthly bleeding level. The doctor also made sure all women were using birth control.

The second clinical study, the Minerva Randomized Study, is currently in progress and involves 153 patients at 13 hospitals and clinics in three countries, including the United States. In this study, the Minerva Endometrial Ablation System is being compared to another treatment for abnormal uterine bleeding called Rollerball ablation.

A randomized study is a study where a computer randomly assigns the patients to one of two treatment groups, the Minerva Endometrial Ablation Device or Rollerball ablation. A total of 153 patients are involved in this study, 102 of them were treated with the Minerva Endometrial Ablation System and 51 were treated with the Rollerball ablation. Unlike the Minerva Single Arm study where women used diaries to measure bleeding levels, this study measured the patient’s bleeding before and after the treatment by collecting and testing the patient’s used sanitary products (tampons and pads). The used sanitary products were sent to a laboratory to measure the amount of blood. The reported patient risks for this ongoing study are available through the 30-day period following treatment and are shown in the Risks table in section IV.

XII. What Were the Results of the Clinical Study?

At one year after the Minerva treatment, 92% of patients had bleeding that was reduced to a normal level or less, and 66% of patients treated completely stopped their monthly periods. 81% of patients reported a decrease in symptoms like moodiness, irritability, vaginal dryness and hot flashes. Over half of the patients (55%) indicated that their monthly cramping decreased after the Minerva treatment. Many patients said they had an improvement in sexual satisfaction.

In this study, of those subjects who answered the survey, the overall patient satisfaction with the procedure was 98%. Nearly 99% of the patients indicated that they would recommend the Minerva procedure to a friend or a relative.

XIII. Where Can You Find Out More About Your Condition?

To find out more about your condition and the Minerva System, please see the Minerva Surgical Website at: www.minervasurgical.com.

Other excellent sources of information are the following:

1. American College of Obstetricians and Gynecologists – provides many useful publications on Women’s Health.

3. The National Women's Health Information Center - The National Women's Health Information Center (NWHIC) is the most reliable and current information resource on women’s health today. NWHIC offers FREE women’s health information on more than 800 topics.
4. Mayo Clinic - Information on Diseases and Conditions, Symptoms, Drugs and Supplements, Tests and procedures, Healthy Lifestyle, First Aid, and other.
