

ZYPREXA[®]
Olanzapine Tablets

ZYPREXA[®] ZYDIS[®]
Olanzapine Orally Disintegrating Tablets

ZYPREXA[®] IntraMuscular
Olanzapine for Injection

WARNING

Increased Mortality in Elderly Patients with Dementia-Related Psychosis — Elderly patients with dementia-related psychosis treated with atypical antipsychotic drugs are at an increased risk of death compared to placebo. Analyses of seventeen placebo-controlled trials (modal duration of 10 weeks) in these patients revealed a risk of death in the drug-treated patients of between 1.6 to 1.7 times that seen in placebo-treated patients. Over the course of a typical 10-week controlled trial, the rate of death in drug-treated patients was about 4.5%, compared to a rate of about 2.6% in the placebo group. Although the causes of death were varied, most of the deaths appeared to be either cardiovascular (e.g., heart failure, sudden death) or infectious (e.g., pneumonia) in nature. ZYPREXA (olanzapine) is not approved for the treatment of patients with dementia-related psychosis (see WARNINGS).

DESCRIPTION

ZYPREXA (olanzapine) is a psychotropic agent that belongs to the thienobenzodiazepine class. The chemical designation is 2-methyl-4-(4-methyl-1-piperazinyl)-10H-thieno[2,3-b][1,5]benzodiazepine. The molecular formula is C₁₇H₂₀N₄S, which corresponds to a molecular weight of 312.44. The chemical structure is:

Olanzapine is a yellow crystalline solid, which is practically insoluble in water.

ZYPREXA tablets are intended for oral administration only.

Each tablet contains olanzapine equivalent to 2.5 mg (8 μmol), 5 mg (16 μmol), 7.5 mg (24 μmol), 10 mg (32 μmol), 15 mg (48 μmol), or 20 mg (64 μmol). Inactive ingredients are carnauba wax, crospovidone, hydroxypropyl cellulose, hypromellose, lactose, magnesium stearate, microcrystalline cellulose, and other inactive ingredients. The color coating contains Titanium Dioxide (all strengths), FD&C Blue No. 2 Aluminum Lake (15 mg), or Synthetic Red Iron Oxide (20 mg). The 2.5, 5, 7.5, and 10 mg tablets are imprinted with edible ink which contains FD&C Blue No. 2 Aluminum Lake.

36 ZYPREXA ZYDIS (olanzapine orally disintegrating tablets) is intended for oral administration
37 only.

38 Each orally disintegrating tablet contains olanzapine equivalent to 5 mg (16 μmol), 10 mg
39 (32 μmol), 15 mg (48 μmol) or 20 mg (64 μmol). It begins disintegrating in the mouth within
40 seconds, allowing its contents to be subsequently swallowed with or without liquid.

41 ZYPREXA ZYDIS (olanzapine orally disintegrating tablets) also contains the following inactive
42 ingredients: gelatin, mannitol, aspartame, sodium methyl paraben and sodium propyl paraben.

43 ZYPREXA IntraMuscular (olanzapine for injection) is intended for intramuscular use only.

44 Each vial provides for the administration of 10 mg (32 μmol) olanzapine with inactive
45 ingredients 50 mg lactose monohydrate and 3.5 mg tartaric acid. Hydrochloric acid and/or
46 sodium hydroxide may have been added during manufacturing to adjust pH.

47 CLINICAL PHARMACOLOGY

48 Pharmacodynamics

49 Olanzapine is a selective monoaminergic antagonist with high affinity binding to the following
50 receptors: serotonin 5HT_{2A/2C}, 5HT₆, ($K_i=4, 11, \text{ and } 5 \text{ nM}$, respectively), dopamine D₁₋₄
51 ($K_i=11\text{-}31 \text{ nM}$), histamine H₁ ($K_i=7 \text{ nM}$), and adrenergic α_1 receptors ($K_i=19 \text{ nM}$). Olanzapine is
52 an antagonist with moderate affinity binding for serotonin 5HT₃ ($K_i=57 \text{ nM}$) and muscarinic M₁₋₅
53 ($K_i=73, 96, 132, 32, \text{ and } 48 \text{ nM}$, respectively). Olanzapine binds weakly to GABA_A, BZD, and
54 β adrenergic receptors ($K_i>10 \mu\text{M}$).

55 The mechanism of action of olanzapine, as with other drugs having efficacy in schizophrenia,
56 is unknown. However, it has been proposed that this drug's efficacy in schizophrenia is mediated
57 through a combination of dopamine and serotonin type 2 (5HT₂) antagonism. The mechanism of
58 action of olanzapine in the treatment of acute manic episodes associated with Bipolar I Disorder
59 is unknown.

60 Antagonism at receptors other than dopamine and 5HT₂ may explain some of the other
61 therapeutic and side effects of olanzapine. Olanzapine's antagonism of muscarinic M₁₋₅ receptors
62 may explain its anticholinergic-like effects. Olanzapine's antagonism of histamine H₁ receptors
63 may explain the somnolence observed with this drug. Olanzapine's antagonism of adrenergic α_1
64 receptors may explain the orthostatic hypotension observed with this drug.

65 Pharmacokinetics

66 Oral Administration

67 Olanzapine is well absorbed and reaches peak concentrations in approximately 6 hours
68 following an oral dose. It is eliminated extensively by first pass metabolism, with approximately
69 40% of the dose metabolized before reaching the systemic circulation. Food does not affect the
70 rate or extent of olanzapine absorption. Pharmacokinetic studies showed that ZYPREXA tablets
71 and ZYPREXA ZYDIS (olanzapine orally disintegrating tablets) dosage forms of olanzapine are
72 bioequivalent.

73 Olanzapine displays linear kinetics over the clinical dosing range. Its half-life ranges from 21 to
74 54 hours (5th to 95th percentile; mean of 30 hr), and apparent plasma clearance ranges from
75 12 to 47 L/hr (5th to 95th percentile; mean of 25 L/hr).

76 Administration of olanzapine once daily leads to steady-state concentrations in about one week
77 that are approximately twice the concentrations after single doses. Plasma concentrations,
78 half-life, and clearance of olanzapine may vary between individuals on the basis of smoking
79 status, gender, and age (*see Special Populations*).

80 Olanzapine is extensively distributed throughout the body, with a volume of distribution of
81 approximately 1000 L. It is 93% bound to plasma proteins over the concentration range of 7 to
82 1100 ng/mL, binding primarily to albumin and α_1 -acid glycoprotein.

83 Metabolism and Elimination — Following a single oral dose of ¹⁴C labeled olanzapine, 7% of
84 the dose of olanzapine was recovered in the urine as unchanged drug, indicating that olanzapine
85 is highly metabolized. Approximately 57% and 30% of the dose was recovered in the urine and
86 feces, respectively. In the plasma, olanzapine accounted for only 12% of the AUC for total
87 radioactivity, indicating significant exposure to metabolites. After multiple dosing, the major
88 circulating metabolites were the 10-N-glucuronide, present at steady state at 44% of the
89 concentration of olanzapine, and 4'-N-desmethyl olanzapine, present at steady state at 31% of the
90 concentration of olanzapine. Both metabolites lack pharmacological activity at the concentrations
91 observed.

92 Direct glucuronidation and cytochrome P450 (CYP) mediated oxidation are the primary
93 metabolic pathways for olanzapine. In vitro studies suggest that CYPs 1A2 and 2D6, and the
94 flavin-containing monooxygenase system are involved in olanzapine oxidation.
95 CYP2D6 mediated oxidation appears to be a minor metabolic pathway in vivo, because the
96 clearance of olanzapine is not reduced in subjects who are deficient in this enzyme.

97 **Intramuscular Administration**

98 ZYPREXA IntraMuscular results in rapid absorption with peak plasma concentrations
99 occurring within 15 to 45 minutes. Based upon a pharmacokinetic study in healthy volunteers, a
100 5 mg dose of intramuscular olanzapine for injection produces, on average, a maximum plasma
101 concentration approximately 5 times higher than the maximum plasma concentration produced
102 by a 5 mg dose of oral olanzapine. Area under the curve achieved after an intramuscular dose is
103 similar to that achieved after oral administration of the same dose. The half-life observed after
104 intramuscular administration is similar to that observed after oral dosing. The pharmacokinetics
105 are linear over the clinical dosing range. Metabolic profiles after intramuscular administration are
106 qualitatively similar to metabolic profiles after oral administration.

107 **Special Populations**

108 Renal Impairment — Because olanzapine is highly metabolized before excretion and only
109 7% of the drug is excreted unchanged, renal dysfunction alone is unlikely to have a major impact
110 on the pharmacokinetics of olanzapine. The pharmacokinetic characteristics of olanzapine were
111 similar in patients with severe renal impairment and normal subjects, indicating that dosage
112 adjustment based upon the degree of renal impairment is not required. In addition, olanzapine is
113 not removed by dialysis. The effect of renal impairment on metabolite elimination has not been
114 studied.

115 Hepatic Impairment — Although the presence of hepatic impairment may be expected to
116 reduce the clearance of olanzapine, a study of the effect of impaired liver function in
117 subjects (n=6) with clinically significant (Childs Pugh Classification A and B) cirrhosis revealed
118 little effect on the pharmacokinetics of olanzapine.

119 Age — In a study involving 24 healthy subjects, the mean elimination half-life of olanzapine
120 was about 1.5 times greater in elderly (>65 years) than in non-elderly subjects (≤65 years).
121 Caution should be used in dosing the elderly, especially if there are other factors that might
122 additively influence drug metabolism and/or pharmacodynamic sensitivity (*see* DOSAGE AND
123 ADMINISTRATION).

124 Gender — Clearance of olanzapine is approximately 30% lower in women than in men. There
125 were, however, no apparent differences between men and women in effectiveness or adverse
126 effects. Dosage modifications based on gender should not be needed.

127 Smoking Status — Olanzapine clearance is about 40% higher in smokers than in nonsmokers,
128 although dosage modifications are not routinely recommended.

129 Race — In vivo studies have shown that exposures are similar among Japanese, Chinese and
130 Caucasians, especially after normalization for body weight differences. Dosage modifications for
131 race are, therefore, not recommended.

132 **Combined Effects** — The combined effects of age, smoking, and gender could lead to
133 substantial pharmacokinetic differences in populations. The clearance in young smoking males,
134 for example, may be 3 times higher than that in elderly nonsmoking females. Dosing
135 modification may be necessary in patients who exhibit a combination of factors that may result in
136 slower metabolism of olanzapine (*see* DOSAGE AND ADMINISTRATION).

137 For specific information about the pharmacology of lithium or valproate, refer to the
138 CLINICAL PHARMACOLOGY section of the package inserts for these other products.

139 **Clinical Efficacy Data**

140 **Schizophrenia**

141 The efficacy of oral olanzapine in the treatment of schizophrenia was established in
142 2 short-term (6-week) controlled trials of inpatients who met DSM III-R criteria for
143 schizophrenia. A single haloperidol arm was included as a comparative treatment in one of the
144 two trials, but this trial did not compare these two drugs on the full range of clinically relevant
145 doses for both.

146 Several instruments were used for assessing psychiatric signs and symptoms in these studies,
147 among them the Brief Psychiatric Rating Scale (BPRS), a multi-item inventory of general
148 psychopathology traditionally used to evaluate the effects of drug treatment in schizophrenia. The
149 BPRS psychosis cluster (conceptual disorganization, hallucinatory behavior, suspiciousness, and
150 unusual thought content) is considered a particularly useful subset for assessing actively
151 psychotic schizophrenic patients. A second traditional assessment, the Clinical Global
152 Impression (CGI), reflects the impression of a skilled observer, fully familiar with the
153 manifestations of schizophrenia, about the overall clinical state of the patient. In addition,
154 two more recently developed scales were employed; these included the 30-item Positive and
155 Negative Symptoms Scale (PANSS), in which are embedded the 18 items of the BPRS, and the
156 Scale for Assessing Negative Symptoms (SANS). The trial summaries below focus on the
157 following outcomes: PANSS total and/or BPRS total; BPRS psychosis cluster; PANSS negative
158 subscale or SANS; and CGI Severity. The results of the trials follow:

159 (1) In a 6-week, placebo-controlled trial (n=149) involving two fixed olanzapine doses of 1 and
160 10 mg/day (once daily schedule), olanzapine, at 10 mg/day (but not at 1 mg/day), was superior to
161 placebo on the PANSS total score (also on the extracted BPRS total), on the BPRS psychosis
162 cluster, on the PANSS Negative subscale, and on CGI Severity.

163 (2) In a 6-week, placebo-controlled trial (n=253) involving 3 fixed dose ranges of olanzapine
164 (5 ± 2.5 mg/day, 10 ± 2.5 mg/day, and 15 ± 2.5 mg/day) on a once daily schedule, the
165 two highest olanzapine dose groups (actual mean doses of 12 and 16 mg/day, respectively) were
166 superior to placebo on BPRS total score, BPRS psychosis cluster, and CGI severity score; the
167 highest olanzapine dose group was superior to placebo on the SANS. There was no clear
168 advantage for the high dose group over the medium dose group.

169 Examination of population subsets (race and gender) did not reveal any differential
170 responsiveness on the basis of these subgroupings.

171 In a longer-term trial, adult outpatients (n=326) who predominantly met DSM-IV criteria for
172 schizophrenia and who remained stable on olanzapine during open label treatment for at least
173 8 weeks were randomized to continuation on their current olanzapine doses (ranging from 10 to
174 20 mg/day) or to placebo. The follow-up period to observe patients for relapse, defined in terms
175 of increases in BPRS positive symptoms or hospitalization, was planned for 12 months, however,
176 criteria were met for stopping the trial early due to an excess of placebo relapses compared to
177 olanzapine relapses, and olanzapine was superior to placebo on time to relapse, the primary
178 outcome for this study. Thus, olanzapine was more effective than placebo at maintaining efficacy
179 in patients stabilized for approximately 8 weeks and followed for an observation period of up to
180 8 months.

181 **Bipolar Disorder**

182 Monotherapy — The efficacy of oral olanzapine in the treatment of acute manic or mixed
183 episodes was established in 2 short-term (one 3-week and one 4-week) placebo-controlled trials
184 in patients who met the DSM-IV criteria for Bipolar I Disorder with manic or mixed episodes.
185 These trials included patients with or without psychotic features and with or without a
186 rapid-cycling course.

187 The primary rating instrument used for assessing manic symptoms in these trials was the
188 Young Mania Rating Scale (Y-MRS), an 11-item clinician-rated scale traditionally used to assess
189 the degree of manic symptomatology (irritability, disruptive/aggressive behavior, sleep, elevated
190 mood, speech, increased activity, sexual interest, language/thought disorder, thought content,
191 appearance, and insight) in a range from 0 (no manic features) to 60 (maximum score). The
192 primary outcome in these trials was change from baseline in the Y-MRS total score. The results
193 of the trials follow:

194 (1) In one 3-week placebo-controlled trial (n=67) which involved a dose range of olanzapine
195 (5-20 mg/day, once daily, starting at 10 mg/day), olanzapine was superior to placebo in the
196 reduction of Y-MRS total score. In an identically designed trial conducted simultaneously with
197 the first trial, olanzapine demonstrated a similar treatment difference, but possibly due to sample
198 size and site variability, was not shown to be superior to placebo on this outcome.

199 (2) In a 4-week placebo-controlled trial (n=115) which involved a dose range of olanzapine
200 (5-20 mg/day, once daily, starting at 15 mg/day), olanzapine was superior to placebo in the
201 reduction of Y-MRS total score.

202 (3) In another trial, 361 patients meeting DSM-IV criteria for a manic or mixed episode of
203 bipolar disorder who had responded during an initial open-label treatment phase for about two
204 weeks, on average, to olanzapine 5 to 20 mg/day were randomized to either continuation of
205 olanzapine at their same dose (n=225) or to placebo (n=136), for observation of relapse.
206 Approximately 50% of the patients had discontinued from the olanzapine group by day 59 and
207 50% of the placebo group had discontinued by day 23 of double-blind treatment. Response
208 during the open-label phase was defined by having a decrease of the Y-MRS total score to ≤ 12
209 and HAM-D 21 to ≤ 8 . Relapse during the double-blind phase was defined as an increase of the
210 Y-MRS or HAM-D 21 total score to ≥ 15 , or being hospitalized for either mania or depression. In
211 the randomized phase, patients receiving continued olanzapine experienced a significantly longer
212 time to relapse.

213 Combination Therapy — The efficacy of oral olanzapine with concomitant lithium or valproate
214 in the treatment of acute manic episodes was established in two controlled trials in patients who
215 met the DSM-IV criteria for Bipolar I Disorder with manic or mixed episodes. These trials
216 included patients with or without psychotic features and with or without a rapid-cycling course.
217 The results of the trials follow:

218 (1) In one 6-week placebo-controlled combination trial, 175 outpatients on lithium or valproate
219 therapy with inadequately controlled manic or mixed symptoms (Y-MRS ≥ 16) were randomized
220 to receive either olanzapine or placebo, in combination with their original therapy. Olanzapine
221 (in a dose range of 5-20 mg/day, once daily, starting at 10 mg/day) combined with lithium or
222 valproate (in a therapeutic range of 0.6 mEq/L to 1.2 mEq/L or 50 $\mu\text{g/mL}$ to 125 $\mu\text{g/mL}$,
223 respectively) was superior to lithium or valproate alone in the reduction of Y-MRS total score.

224 (2) In a second 6-week placebo-controlled combination trial, 169 outpatients on lithium or
225 valproate therapy with inadequately controlled manic or mixed symptoms (Y-MRS ≥ 16) were
226 randomized to receive either olanzapine or placebo, in combination with their original therapy.
227 Olanzapine (in a dose range of 5-20 mg/day, once daily, starting at 10 mg/day) combined with
228 lithium or valproate (in a therapeutic range of 0.6 mEq/L to 1.2 mEq/L or 50 $\mu\text{g/mL}$ to
229 125 $\mu\text{g/mL}$, respectively) was superior to lithium or valproate alone in the reduction of Y-MRS
230 total score.

231 **Agitation Associated with Schizophrenia and Bipolar I Mania**

232 The efficacy of intramuscular olanzapine for injection for the treatment of agitation was
 233 established in 3 short-term (24 hours of IM treatment) placebo-controlled trials in agitated
 234 inpatients from two diagnostic groups: schizophrenia and Bipolar I Disorder (manic or mixed
 235 episodes). Each of the trials included a single active comparator treatment arm of either
 236 haloperidol injection (schizophrenia studies) or lorazepam injection (bipolar mania study).
 237 Patients enrolled in the trials needed to be: (1) judged by the clinical investigators as clinically
 238 agitated and clinically appropriate candidates for treatment with intramuscular medication, and
 239 (2) exhibiting a level of agitation that met or exceeded a threshold score of ≥ 14 on the five items
 240 comprising the Positive and Negative Syndrome Scale (PANSS) Excited Component (i.e., poor
 241 impulse control, tension, hostility, uncooperativeness and excitement items) with at least
 242 one individual item score ≥ 4 using a 1-7 scoring system (1=absent, 4=moderate, 7=extreme). In
 243 the studies, the mean baseline PANSS Excited Component score was 18.4, with scores ranging
 244 from 13 to 32 (out of a maximum score of 35), thus suggesting predominantly moderate levels of
 245 agitation with some patients experiencing mild or severe levels of agitation. The primary efficacy
 246 measure used for assessing agitation signs and symptoms in these trials was the change from
 247 baseline in the PANSS Excited Component at 2 hours post-injection. Patients could receive up to
 248 three injections during the 24 hour IM treatment periods; however, patients could not receive the
 249 second injection until after the initial 2 hour period when the primary efficacy measure was
 250 assessed. The results of the trials follow:

251 (1) In a placebo-controlled trial in agitated inpatients meeting DSM-IV criteria for
 252 schizophrenia (n=270), four fixed intramuscular olanzapine for injection doses of 2.5 mg, 5 mg,
 253 7.5 mg and 10 mg were evaluated. All doses were statistically superior to placebo on the PANSS
 254 Excited Component at 2 hours post-injection. However, the effect was larger and more consistent
 255 for the three highest doses. There were no significant pairwise differences for the 7.5 and 10 mg
 256 doses over the 5 mg dose.

257 (2) In a second placebo-controlled trial in agitated inpatients meeting DSM-IV criteria for
 258 schizophrenia (n=311), one fixed intramuscular olanzapine for injection dose of 10 mg was
 259 evaluated. Olanzapine for injection was statistically superior to placebo on the PANSS Excited
 260 Component at 2 hours post-injection.

261 (3) In a placebo-controlled trial in agitated inpatients meeting DSM-IV criteria for Bipolar I
 262 Disorder (and currently displaying an acute manic or mixed episode with or without psychotic
 263 features) (n=201), one fixed intramuscular olanzapine for injection dose of 10 mg was evaluated.
 264 Olanzapine for injection was statistically superior to placebo on the PANSS Excited Component
 265 at 2 hours post-injection.

266 Examination of population subsets (age, race, and gender) did not reveal any differential
 267 responsiveness on the basis of these subgroupings.

268 **INDICATIONS AND USAGE**

269 **Schizophrenia**

270 Oral ZYPREXA is indicated for the treatment of schizophrenia.

271 The efficacy of ZYPREXA was established in short-term (6-week) controlled trials of
 272 schizophrenic inpatients (*see* CLINICAL PHARMACOLOGY).

273 The effectiveness of oral ZYPREXA at maintaining a treatment response in schizophrenic
 274 patients who had been stable on ZYPREXA for approximately 8 weeks and were then followed
 275 for a period of up to 8 months has been demonstrated in a placebo-controlled trial (*see*
 276 CLINICAL PHARMACOLOGY). Nevertheless, the physician who elects to use ZYPREXA for
 277 extended periods should periodically re-evaluate the long-term usefulness of the drug for the
 278 individual patient (*see* DOSAGE AND ADMINISTRATION).

279 **Bipolar Disorder**

280 Acute Monotherapy — Oral ZYPREXA is indicated for the treatment of acute mixed or manic
281 episodes associated with Bipolar I Disorder.

282 The efficacy of ZYPREXA was established in two placebo-controlled trials (one 3-week and
283 one 4-week) with patients meeting DSM-IV criteria for Bipolar I Disorder who currently
284 displayed an acute manic or mixed episode with or without psychotic features (*see* CLINICAL
285 PHARMACOLOGY).

286 Maintenance Monotherapy — The benefit of maintaining bipolar patients on monotherapy with
287 oral ZYPREXA after achieving a responder status for an average duration of two weeks was
288 demonstrated in a controlled trial (*see* Clinical Efficacy Data *under* CLINICAL
289 PHARMACOLOGY). The physician who elects to use ZYPREXA for extended periods should
290 periodically re-evaluate the long-term usefulness of the drug for the individual patient (*see*
291 DOSAGE AND ADMINISTRATION).

292 Combination Therapy — The combination of oral ZYPREXA with lithium or valproate is
293 indicated for the short-term treatment of acute mixed or manic episodes associated with Bipolar I
294 Disorder.

295 The efficacy of ZYPREXA in combination with lithium or valproate was established in
296 two placebo-controlled (6-week) trials with patients meeting DSM-IV criteria for Bipolar I
297 Disorder who currently displayed an acute manic or mixed episode with or without psychotic
298 features (*see* CLINICAL PHARMACOLOGY).

299 **Agitation Associated with Schizophrenia and Bipolar I Mania**

300 ZYPREXA IntraMuscular is indicated for the treatment of agitation associated with
301 schizophrenia and bipolar I mania. “Psychomotor agitation” is defined in DSM-IV as “excessive
302 motor activity associated with a feeling of inner tension.” Patients experiencing agitation often
303 manifest behaviors that interfere with their diagnosis and care, e.g., threatening behaviors,
304 escalating or urgently distressing behavior, or self-exhausting behavior, leading clinicians to the
305 use of intramuscular antipsychotic medications to achieve immediate control of the agitation.

306 The efficacy of ZYPREXA IntraMuscular for the treatment of agitation associated with
307 schizophrenia and bipolar I mania was established in 3 short-term (24 hours) placebo-controlled
308 trials in agitated inpatients with schizophrenia or Bipolar I Disorder (manic or mixed episodes)
309 (*see* CLINICAL PHARMACOLOGY).

310 **CONTRAINDICATIONS**

311 ZYPREXA is contraindicated in patients with a known hypersensitivity to the product.

312 For specific information about the contraindications of lithium or valproate, refer to the
313 CONTRAINDICATIONS section of the package inserts for these other products.

314 **WARNINGS**

315 **Increased Mortality in Elderly Patients with Dementia-Related Psychosis — Elderly**
316 **patients with dementia-related psychosis treated with atypical antipsychotic drugs are at**
317 **an increased risk of death compared to placebo. ZYPREXA is not approved for the**
318 **treatment of patients with dementia-related psychosis (*see* BOX WARNING).**

319 In placebo-controlled clinical trials of elderly patients with dementia-related psychosis, the
320 incidence of death in olanzapine-treated patients was significantly greater than placebo-treated
321 patients (3.5% vs 1.5%, respectively).

322 Cerebrovascular Adverse Events, Including Stroke, in Elderly Patients with Dementia-Related
323 Psychosis — Cerebrovascular adverse events (e.g., stroke, transient ischemic attack), including
324 fatalities, were reported in patients in trials of olanzapine in elderly patients with
325 dementia-related psychosis. In placebo-controlled trials, there was a significantly higher
326 incidence of cerebrovascular adverse events in patients treated with olanzapine compared to

327 patients treated with placebo. Olanzapine is not approved for the treatment of patients with
328 dementia-related psychosis.

329 Hyperglycemia and Diabetes Mellitus — Hyperglycemia, in some cases extreme and associated
330 with ketoacidosis or hyperosmolar coma or death, has been reported in patients treated with
331 atypical antipsychotics including olanzapine. Assessment of the relationship between atypical
332 antipsychotic use and glucose abnormalities is complicated by the possibility of an increased
333 background risk of diabetes mellitus in patients with schizophrenia and the increasing incidence
334 of diabetes mellitus in the general population. Given these confounders, the relationship between
335 atypical antipsychotic use and hyperglycemia-related adverse events is not completely
336 understood. However, epidemiological studies suggest an increased risk of treatment-emergent
337 hyperglycemia-related adverse events in patients treated with the atypical antipsychotics. Precise
338 risk estimates for hyperglycemia-related adverse events in patients treated with atypical
339 antipsychotics are not available.

340 Patients with an established diagnosis of diabetes mellitus who are started on atypical
341 antipsychotics should be monitored regularly for worsening of glucose control. Patients with risk
342 factors for diabetes mellitus (e.g., obesity, family history of diabetes) who are starting treatment
343 with atypical antipsychotics should undergo fasting blood glucose testing at the beginning of
344 treatment and periodically during treatment. Any patient treated with atypical antipsychotics
345 should be monitored for symptoms of hyperglycemia including polydipsia, polyuria, polyphagia,
346 and weakness. Patients who develop symptoms of hyperglycemia during treatment with atypical
347 antipsychotics should undergo fasting blood glucose testing. In some cases, hyperglycemia has
348 resolved when the atypical antipsychotic was discontinued; however, some patients required
349 continuation of anti-diabetic treatment despite discontinuation of the suspect drug.

350 Neuroleptic Malignant Syndrome (NMS) — A potentially fatal symptom complex sometimes
351 referred to as Neuroleptic Malignant Syndrome (NMS) has been reported in association with
352 administration of antipsychotic drugs, including olanzapine. Clinical manifestations of NMS are
353 hyperpyrexia, muscle rigidity, altered mental status and evidence of autonomic instability
354 (irregular pulse or blood pressure, tachycardia, diaphoresis and cardiac dysrhythmia). Additional
355 signs may include elevated creatinine phosphokinase, myoglobinuria (rhabdomyolysis), and acute
356 renal failure.

357 The diagnostic evaluation of patients with this syndrome is complicated. In arriving at a
358 diagnosis, it is important to exclude cases where the clinical presentation includes both serious
359 medical illness (e.g., pneumonia, systemic infection, etc.) and untreated or inadequately treated
360 extrapyramidal signs and symptoms (EPS). Other important considerations in the differential
361 diagnosis include central anticholinergic toxicity, heat stroke, drug fever, and primary central
362 nervous system pathology.

363 The management of NMS should include: 1) immediate discontinuation of antipsychotic drugs
364 and other drugs not essential to concurrent therapy; 2) intensive symptomatic treatment and
365 medical monitoring; and 3) treatment of any concomitant serious medical problems for which
366 specific treatments are available. There is no general agreement about specific pharmacological
367 treatment regimens for NMS.

368 If a patient requires antipsychotic drug treatment after recovery from NMS, the potential
369 reintroduction of drug therapy should be carefully considered. The patient should be carefully
370 monitored, since recurrences of NMS have been reported.

371 Tardive Dyskinesia — A syndrome of potentially irreversible, involuntary, dyskinetic
372 movements may develop in patients treated with antipsychotic drugs. Although the prevalence of
373 the syndrome appears to be highest among the elderly, especially elderly women, it is impossible
374 to rely upon prevalence estimates to predict, at the inception of antipsychotic treatment, which
375 patients are likely to develop the syndrome. Whether antipsychotic drug products differ in their
376 potential to cause tardive dyskinesia is unknown.

377 The risk of developing tardive dyskinesia and the likelihood that it will become irreversible are
378 believed to increase as the duration of treatment and the total cumulative dose of antipsychotic
379 drugs administered to the patient increase. However, the syndrome can develop, although much
380 less commonly, after relatively brief treatment periods at low doses.

381 There is no known treatment for established cases of tardive dyskinesia, although the syndrome
382 may remit, partially or completely, if antipsychotic treatment is withdrawn. Antipsychotic
383 treatment, itself, however, may suppress (or partially suppress) the signs and symptoms of the
384 syndrome and thereby may possibly mask the underlying process. The effect that symptomatic
385 suppression has upon the long-term course of the syndrome is unknown.

386 Given these considerations, olanzapine should be prescribed in a manner that is most likely to
387 minimize the occurrence of tardive dyskinesia. Chronic antipsychotic treatment should generally
388 be reserved for patients (1) who suffer from a chronic illness that is known to respond to
389 antipsychotic drugs, and (2) for whom alternative, equally effective, but potentially less harmful
390 treatments are not available or appropriate. In patients who do require chronic treatment, the
391 smallest dose and the shortest duration of treatment producing a satisfactory clinical response
392 should be sought. The need for continued treatment should be reassessed periodically.

393 If signs and symptoms of tardive dyskinesia appear in a patient on olanzapine, drug
394 discontinuation should be considered. However, some patients may require treatment with
395 olanzapine despite the presence of the syndrome.

396 For specific information about the warnings of lithium or valproate, refer to the WARNINGS
397 section of the package inserts for these other products.

398

PRECAUTIONS

399 **General**

400 Hemodynamic Effects — Olanzapine may induce orthostatic hypotension associated with
401 dizziness, tachycardia, and in some patients, syncope, especially during the initial dose-titration
402 period, probably reflecting its α_1 -adrenergic antagonistic properties. Hypotension, bradycardia
403 with or without hypotension, tachycardia, and syncope were also reported during the clinical
404 trials with intramuscular olanzapine for injection. In an open-label clinical pharmacology study in
405 non-agitated patients with schizophrenia in which the safety and tolerability of intramuscular
406 olanzapine were evaluated under a maximal dosing regimen (three 10 mg doses administered
407 4 hours apart), approximately one-third of these patients experienced a significant orthostatic
408 decrease in systolic blood pressure (i.e., decrease ≥ 30 mmHg) (*see* DOSAGE AND
409 ADMINISTRATION). Syncope was reported in 0.6% (15/2500) of olanzapine-treated patients in
410 phase 2-3 oral olanzapine studies and in 0.3% (2/722) of olanzapine-treated patients with
411 agitation in the intramuscular olanzapine for injection studies. Three normal volunteers in
412 phase 1 studies with intramuscular olanzapine experienced hypotension, bradycardia, and sinus
413 pauses of up to 6 seconds that spontaneously resolved (in 2 cases the events occurred on
414 intramuscular olanzapine, and in 1 case, on oral olanzapine). The risk for this sequence of
415 hypotension, bradycardia, and sinus pause may be greater in nonpsychiatric patients compared to
416 psychiatric patients who are possibly more adapted to certain effects of psychotropic drugs.

417 For oral olanzapine therapy, the risk of orthostatic hypotension and syncope may be minimized
418 by initiating therapy with 5 mg QD (*see* DOSAGE AND ADMINISTRATION). A more gradual
419 titration to the target dose should be considered if hypotension occurs.

420 For intramuscular olanzapine for injection therapy, patients should remain recumbent if drowsy
421 or dizzy after injection until examination has indicated that they are not experiencing postural
422 hypotension, bradycardia, and/or hypoventilation.

423 Olanzapine should be used with particular caution in patients with known cardiovascular
424 disease (history of myocardial infarction or ischemia, heart failure, or conduction abnormalities),
425 cerebrovascular disease, and conditions which would predispose patients to hypotension

426 (dehydration, hypovolemia, and treatment with antihypertensive medications) where the
427 occurrence of syncope, or hypotension and/or bradycardia might put the patient at increased
428 medical risk.

429 Caution is necessary in patients who receive treatment with other drugs having effects that can
430 induce hypotension, bradycardia, respiratory or central nervous system depression (*see Drug*
431 *Interactions*). Concomitant administration of intramuscular olanzapine and parenteral
432 benzodiazepine has not been studied and is therefore not recommended. If use of intramuscular
433 olanzapine in combination with parenteral benzodiazepines is considered, careful evaluation of
434 clinical status for excessive sedation and cardiorespiratory depression is recommended.

435 Seizures — During premarketing testing, seizures occurred in 0.9% (22/2500) of
436 olanzapine-treated patients. There were confounding factors that may have contributed to the
437 occurrence of seizures in many of these cases. Olanzapine should be used cautiously in patients
438 with a history of seizures or with conditions that potentially lower the seizure threshold,
439 e.g., Alzheimer's dementia. Conditions that lower the seizure threshold may be more prevalent in
440 a population of 65 years or older.

441 Hyperprolactinemia — As with other drugs that antagonize dopamine D₂ receptors, olanzapine
442 elevates prolactin levels, and a modest elevation persists during chronic administration. Tissue
443 culture experiments indicate that approximately one-third of human breast cancers are prolactin
444 dependent in vitro, a factor of potential importance if the prescription of these drugs is
445 contemplated in a patient with previously detected breast cancer of this type. Although
446 disturbances such as galactorrhea, amenorrhea, gynecomastia, and impotence have been reported
447 with prolactin-elevating compounds, the clinical significance of elevated serum prolactin levels
448 is unknown for most patients. As is common with compounds which increase prolactin release,
449 an increase in mammary gland neoplasia was observed in the olanzapine carcinogenicity studies
450 conducted in mice and rats (*see Carcinogenesis*). However, neither clinical studies nor
451 epidemiologic studies have shown an association between chronic administration of this class of
452 drugs and tumorigenesis in humans; the available evidence is considered too limited to be
453 conclusive.

454 Transaminase Elevations — In placebo-controlled studies, clinically significant ALT (SGPT)
455 elevations (≥ 3 times the upper limit of the normal range) were observed in 2% (6/243) of patients
456 exposed to olanzapine compared to none (0/115) of the placebo patients. None of these patients
457 experienced jaundice. In two of these patients, liver enzymes decreased toward normal despite
458 continued treatment and in two others, enzymes decreased upon discontinuation of olanzapine. In
459 the remaining two patients, one, seropositive for hepatitis C, had persistent enzyme elevation for
460 four months after discontinuation, and the other had insufficient follow-up to determine if
461 enzymes normalized.

462 Within the larger premarketing database of about 2400 patients with baseline SGPT ≤ 90 IU/L,
463 the incidence of SGPT elevation to >200 IU/L was 2% (50/2381). Again, none of these patients
464 experienced jaundice or other symptoms attributable to liver impairment and most had transient
465 changes that tended to normalize while olanzapine treatment was continued.

466 Among 2500 patients in oral olanzapine clinical trials, about 1% (23/2500) discontinued
467 treatment due to transaminase increases.

468 Caution should be exercised in patients with signs and symptoms of hepatic impairment, in
469 patients with pre-existing conditions associated with limited hepatic functional reserve, and in
470 patients who are being treated with potentially hepatotoxic drugs. Periodic assessment of
471 transaminases is recommended in patients with significant hepatic disease (*see Laboratory Tests*).

472 Potential for Cognitive and Motor Impairment — Somnolence was a commonly reported
473 adverse event associated with olanzapine treatment, occurring at an incidence of 26% in
474 olanzapine patients compared to 15% in placebo patients. This adverse event was also dose

475 related. Somnolence led to discontinuation in 0.4% (9/2500) of patients in the premarketing
476 database.

477 Since olanzapine has the potential to impair judgment, thinking, or motor skills, patients should
478 be cautioned about operating hazardous machinery, including automobiles, until they are
479 reasonably certain that olanzapine therapy does not affect them adversely.

480 Body Temperature Regulation — Disruption of the body's ability to reduce core body
481 temperature has been attributed to antipsychotic agents. Appropriate care is advised when
482 prescribing olanzapine for patients who will be experiencing conditions which may contribute to
483 an elevation in core body temperature, e.g., exercising strenuously, exposure to extreme heat,
484 receiving concomitant medication with anticholinergic activity, or being subject to dehydration.

485 Dysphagia — Esophageal dysmotility and aspiration have been associated with antipsychotic
486 drug use. Aspiration pneumonia is a common cause of morbidity and mortality in patients with
487 advanced Alzheimer's disease. Olanzapine and other antipsychotic drugs should be used
488 cautiously in patients at risk for aspiration pneumonia.

489 Suicide — The possibility of a suicide attempt is inherent in schizophrenia and in bipolar
490 disorder, and close supervision of high-risk patients should accompany drug therapy.
491 Prescriptions for olanzapine should be written for the smallest quantity of tablets consistent with
492 good patient management, in order to reduce the risk of overdose.

493 Use in Patients with Concomitant Illness — Clinical experience with olanzapine in patients
494 with certain concomitant systemic illnesses (*see* Renal Impairment and Hepatic Impairment
495 *under* CLINICAL PHARMACOLOGY, Special Populations) is limited.

496 Olanzapine exhibits in vitro muscarinic receptor affinity. In premarketing clinical trials with
497 olanzapine, olanzapine was associated with constipation, dry mouth, and tachycardia, all adverse
498 events possibly related to cholinergic antagonism. Such adverse events were not often the basis
499 for discontinuations from olanzapine, but olanzapine should be used with caution in patients with
500 clinically significant prostatic hypertrophy, narrow angle glaucoma, or a history of paralytic ileus.

501 In five placebo-controlled studies of olanzapine in elderly patients with dementia-related
502 psychosis (n=1184), the following treatment-emergent adverse events were reported in
503 olanzapine-treated patients at an incidence of at least 2% and significantly greater than
504 placebo-treated patients: falls, somnolence, peripheral edema, abnormal gait, urinary
505 incontinence, lethargy, increased weight, asthenia, pyrexia, pneumonia, dry mouth and visual
506 hallucinations. The rate of discontinuation due to adverse events was significantly greater with
507 olanzapine than placebo (13% vs 7%). Elderly patients with dementia-related psychosis treated
508 with olanzapine are at an increased risk of death compared to placebo. Olanzapine is not
509 approved for the treatment of patients with dementia-related psychosis. If the prescriber elects to
510 treat elderly patients with dementia-related psychosis, vigilance should be exercised (*see* BOX
511 WARNING and WARNINGS).

512 Olanzapine has not been evaluated or used to any appreciable extent in patients with a recent
513 history of myocardial infarction or unstable heart disease. Patients with these diagnoses were
514 excluded from premarketing clinical studies. Because of the risk of orthostatic hypotension with
515 olanzapine, caution should be observed in cardiac patients (*see* Hemodynamic Effects).

516 For specific information about the precautions of lithium or valproate, refer to the
517 PRECAUTIONS section of the package inserts for these other products.

518 **Information for Patients**

519 Physicians are advised to discuss the following issues with patients for whom they prescribe
520 olanzapine:

521 Orthostatic Hypotension — Patients should be advised of the risk of orthostatic hypotension,
522 especially during the period of initial dose titration and in association with the use of

523 concomitant drugs that may potentiate the orthostatic effect of olanzapine, e.g., diazepam or
524 alcohol (*see* Drug Interactions).

525 Interference with Cognitive and Motor Performance — Because olanzapine has the potential to
526 impair judgment, thinking, or motor skills, patients should be cautioned about operating
527 hazardous machinery, including automobiles, until they are reasonably certain that olanzapine
528 therapy does not affect them adversely.

529 Pregnancy — Patients should be advised to notify their physician if they become pregnant or
530 intend to become pregnant during therapy with olanzapine.

531 Nursing — Patients should be advised not to breast-feed an infant if they are taking olanzapine.

532 Concomitant Medication — Patients should be advised to inform their physicians if they are
533 taking, or plan to take, any prescription or over-the-counter drugs, since there is a potential for
534 interactions.

535 Alcohol — Patients should be advised to avoid alcohol while taking olanzapine.

536 Heat Exposure and Dehydration — Patients should be advised regarding appropriate care in
537 avoiding overheating and dehydration.

538 Phenylketonurics — ZYPREXA ZYDIS (olanzapine orally disintegrating tablets) contains
539 phenylalanine (0.34, 0.45, 0.67, or 0.90 mg per 5, 10, 15, or 20 mg tablet, respectively).

540 **Laboratory Tests**

541 Periodic assessment of transaminases is recommended in patients with significant hepatic
542 disease (*see* Transaminase Elevations).

543 **Drug Interactions**

544 The risks of using olanzapine in combination with other drugs have not been extensively
545 evaluated in systematic studies. Given the primary CNS effects of olanzapine, caution should be
546 used when olanzapine is taken in combination with other centrally acting drugs and alcohol.

547 Because of its potential for inducing hypotension, olanzapine may enhance the effects of
548 certain antihypertensive agents.

549 Olanzapine may antagonize the effects of levodopa and dopamine agonists.

550 The Effect of Other Drugs on Olanzapine — Agents that induce CYP1A2 or glucuronyl
551 transferase enzymes, such as omeprazole and rifampin, may cause an increase in olanzapine
552 clearance. Inhibitors of CYP1A2 could potentially inhibit olanzapine clearance. Although
553 olanzapine is metabolized by multiple enzyme systems, induction or inhibition of a
554 single enzyme may appreciably alter olanzapine clearance. Therefore, a dosage increase (for
555 induction) or a dosage decrease (for inhibition) may need to be considered with specific drugs.

556 Charcoal — The administration of activated charcoal (1 g) reduced the C_{max} and AUC of oral
557 olanzapine by about 60%. As peak olanzapine levels are not typically obtained until about
558 6 hours after dosing, charcoal may be a useful treatment for olanzapine overdose.

559 Cimetidine and Antacids — Single doses of cimetidine (800 mg) or aluminum- and
560 magnesium-containing antacids did not affect the oral bioavailability of olanzapine.

561 Carbamazepine — Carbamazepine therapy (200 mg bid) causes an approximately 50% increase
562 in the clearance of olanzapine. This increase is likely due to the fact that carbamazepine is a
563 potent inducer of CYP1A2 activity. Higher daily doses of carbamazepine may cause an even
564 greater increase in olanzapine clearance.

565 Ethanol — Ethanol (45 mg/70 kg single dose) did not have an effect on olanzapine
566 pharmacokinetics.

567 Fluoxetine — Fluoxetine (60 mg single dose or 60 mg daily for 8 days) causes a small
568 (mean 16%) increase in the maximum concentration of olanzapine and a small (mean 16%)
569 decrease in olanzapine clearance. The magnitude of the impact of this factor is small in

570 comparison to the overall variability between individuals, and therefore dose modification is not
571 routinely recommended.

572 Fluvoxamine — Fluvoxamine, a CYP1A2 inhibitor, decreases the clearance of olanzapine.
573 This results in a mean increase in olanzapine C_{max} following fluvoxamine of 54% in female
574 nonsmokers and 77% in male smokers. The mean increase in olanzapine AUC is 52% and 108%,
575 respectively. Lower doses of olanzapine should be considered in patients receiving concomitant
576 treatment with fluvoxamine.

577 Warfarin — Warfarin (20 mg single dose) did not affect olanzapine pharmacokinetics.

578 Effect of Olanzapine on Other Drugs — In vitro studies utilizing human liver microsomes
579 suggest that olanzapine has little potential to inhibit CYP1A2, CYP2C9, CYP2C19, CYP2D6,
580 and CYP3A. Thus, olanzapine is unlikely to cause clinically important drug interactions
581 mediated by these enzymes.

582 Lithium — Multiple doses of olanzapine (10 mg for 8 days) did not influence the kinetics of
583 lithium. Therefore, concomitant olanzapine administration does not require dosage adjustment of
584 lithium.

585 Valproate — Studies in vitro using human liver microsomes determined that olanzapine has
586 little potential to inhibit the major metabolic pathway, glucuronidation, of valproate. Further,
587 valproate has little effect on the metabolism of olanzapine in vitro. In vivo administration of
588 olanzapine (10 mg daily for 2 weeks) did not affect the steady state plasma concentrations of
589 valproate. Therefore, concomitant olanzapine administration does not require dosage adjustment
590 of valproate.

591 Single doses of olanzapine did not affect the pharmacokinetics of imipramine or its active
592 metabolite desipramine, and warfarin. Multiple doses of olanzapine did not influence the kinetics
593 of diazepam and its active metabolite N-desmethyldiazepam, ethanol, or biperiden. However, the
594 co-administration of either diazepam or ethanol with olanzapine potentiated the orthostatic
595 hypotension observed with olanzapine. Multiple doses of olanzapine did not affect the
596 pharmacokinetics of theophylline or its metabolites.

597 Lorazepam — Administration of intramuscular lorazepam (2 mg) 1 hour after intramuscular
598 olanzapine for injection (5 mg) did not significantly affect the pharmacokinetics of olanzapine,
599 unconjugated lorazepam, or total lorazepam. However, this co-administration of intramuscular
600 lorazepam and intramuscular olanzapine for injection added to the somnolence observed with
601 either drug alone (*see Hemodynamic Effects*).

602 **Carcinogenesis, Mutagenesis, Impairment of Fertility**

603 Carcinogenesis — Oral carcinogenicity studies were conducted in mice and rats. Olanzapine
604 was administered to mice in two 78-week studies at doses of 3, 10, 30/20 mg/kg/day (equivalent
605 to 0.8-5 times the maximum recommended human daily oral dose on a mg/m² basis) and 0.25, 2,
606 8 mg/kg/day (equivalent to 0.06-2 times the maximum recommended human daily oral dose on a
607 mg/m² basis). Rats were dosed for 2 years at doses of 0.25, 1, 2.5, 4 mg/kg/day (males) and 0.25,
608 1, 4, 8 mg/kg/day (females) (equivalent to 0.13-2 and 0.13-4 times the maximum recommended
609 human daily oral dose on a mg/m² basis, respectively). The incidence of liver hemangiomas and
610 hemangiosarcomas was significantly increased in one mouse study in female mice dosed at
611 8 mg/kg/day (2 times the maximum recommended human daily oral dose on a mg/m² basis).
612 These tumors were not increased in another mouse study in females dosed at 10 or
613 30/20 mg/kg/day (2-5 times the maximum recommended human daily oral dose on a mg/m²
614 basis); in this study, there was a high incidence of early mortalities in males of the
615 30/20 mg/kg/day group. The incidence of mammary gland adenomas and adenocarcinomas was
616 significantly increased in female mice dosed at ≥2 mg/kg/day and in female rats dosed at
617 ≥4 mg/kg/day (0.5 and 2 times the maximum recommended human daily oral dose on a mg/m²
618 basis, respectively). Antipsychotic drugs have been shown to chronically elevate prolactin levels
619 in rodents. Serum prolactin levels were not measured during the olanzapine carcinogenicity

620 studies; however, measurements during subchronic toxicity studies showed that olanzapine
621 elevated serum prolactin levels up to 4-fold in rats at the same doses used in the carcinogenicity
622 study. An increase in mammary gland neoplasms has been found in rodents after chronic
623 administration of other antipsychotic drugs and is considered to be prolactin mediated. The
624 relevance for human risk of the finding of prolactin mediated endocrine tumors in rodents is
625 unknown (*see* Hyperprolactinemia *under* PRECAUTIONS, General).

626 Mutagenesis — No evidence of mutagenic potential for olanzapine was found in the Ames
627 reverse mutation test, in vivo micronucleus test in mice, the chromosomal aberration test in
628 Chinese hamster ovary cells, unscheduled DNA synthesis test in rat hepatocytes, induction of
629 forward mutation test in mouse lymphoma cells, or in vivo sister chromatid exchange test in bone
630 marrow of Chinese hamsters.

631 Impairment of Fertility — In an oral fertility and reproductive performance study in rats, male
632 mating performance, but not fertility, was impaired at a dose of 22.4 mg/kg/day and female
633 fertility was decreased at a dose of 3 mg/kg/day (11 and 1.5 times the maximum recommended
634 human daily oral dose on a mg/m² basis, respectively). Discontinuance of olanzapine treatment
635 reversed the effects on male mating performance. In female rats, the precoital period was
636 increased and the mating index reduced at 5 mg/kg/day (2.5 times the maximum recommended
637 human daily oral dose on a mg/m² basis). Diestrus was prolonged and estrus delayed at
638 1.1 mg/kg/day (0.6 times the maximum recommended human daily oral dose on a mg/m² basis);
639 therefore olanzapine may produce a delay in ovulation.

640 **Pregnancy**

641 Pregnancy Category C — In oral reproduction studies in rats at doses up to 18 mg/kg/day and
642 in rabbits at doses up to 30 mg/kg/day (9 and 30 times the maximum recommended human daily
643 oral dose on a mg/m² basis, respectively) no evidence of teratogenicity was observed. In an oral
644 rat teratology study, early resorptions and increased numbers of nonviable fetuses were observed
645 at a dose of 18 mg/kg/day (9 times the maximum recommended human daily oral dose on a
646 mg/m² basis). Gestation was prolonged at 10 mg/kg/day (5 times the maximum recommended
647 human daily oral dose on a mg/m² basis). In an oral rabbit teratology study, fetal toxicity
648 (manifested as increased resorptions and decreased fetal weight) occurred at a maternally toxic
649 dose of 30 mg/kg/day (30 times the maximum recommended human daily oral dose on a mg/m²
650 basis).

651 Placental transfer of olanzapine occurs in rat pups.

652 There are no adequate and well-controlled trials with olanzapine in pregnant females.
653 Seven pregnancies were observed during clinical trials with olanzapine, including 2 resulting in
654 normal births, 1 resulting in neonatal death due to a cardiovascular defect, 3 therapeutic
655 abortions, and 1 spontaneous abortion. Because animal reproduction studies are not always
656 predictive of human response, this drug should be used during pregnancy only if the potential
657 benefit justifies the potential risk to the fetus.

658 **Labor and Delivery**

659 Parturition in rats was not affected by olanzapine. The effect of olanzapine on labor and
660 delivery in humans is unknown.

661 **Nursing Mothers**

662 In a study in lactating, healthy women, olanzapine was excreted in breast milk. Mean infant
663 dose at steady state was estimated to be 1.8% of the maternal olanzapine dose. It is recommended
664 that women receiving olanzapine should not breast-feed.

665 **Pediatric Use**

666 Safety and effectiveness in pediatric patients have not been established.

667 **Geriatric Use**

668 Of the 2500 patients in premarketing clinical studies with oral olanzapine, 11% (263) were
669 65 years of age or over. In patients with schizophrenia, there was no indication of any different
670 tolerability of olanzapine in the elderly compared to younger patients. Studies in elderly patients
671 with dementia-related psychosis have suggested that there may be a different tolerability profile
672 in this population compared to younger patients with schizophrenia. Elderly patients with
673 dementia-related psychosis treated with olanzapine are at an increased risk of death compared to
674 placebo. Olanzapine is not approved for the treatment of patients with dementia-related
675 psychosis. If the prescriber elects to treat elderly patients with dementia-related psychosis,
676 vigilance should be exercised. Also, the presence of factors that might decrease pharmacokinetic
677 clearance or increase the pharmacodynamic response to olanzapine should lead to consideration
678 of a lower starting dose for any geriatric patient (*see* BOX WARNING, WARNINGS,
679 PRECAUTIONS, *and* DOSAGE AND ADMINISTRATION).

680 **ADVERSE REACTIONS**

681 The information below is derived from a clinical trial database for olanzapine consisting of
682 8661 patients with approximately 4165 patient-years of exposure to oral olanzapine and
683 722 patients with exposure to intramuscular olanzapine for injection. This database includes:
684 (1) 2500 patients who participated in multiple-dose oral olanzapine premarketing trials in
685 schizophrenia and Alzheimer's disease representing approximately 1122 patient-years of
686 exposure as of February 14, 1995; (2) 182 patients who participated in oral olanzapine
687 premarketing bipolar mania trials representing approximately 66 patient-years of exposure;
688 (3) 191 patients who participated in an oral olanzapine trial of patients having various psychiatric
689 symptoms in association with Alzheimer's disease representing approximately 29 patient-years
690 of exposure; (4) 5788 patients from 88 additional oral olanzapine clinical trials as of
691 December 31, 2001; and (5) 722 patients who participated in intramuscular olanzapine for
692 injection premarketing trials in agitated patients with schizophrenia, Bipolar I Disorder (manic or
693 mixed episodes), or dementia. In addition, information from the premarketing 6-week clinical
694 study database for olanzapine in combination with lithium or valproate, consisting of
695 224 patients who participated in bipolar mania trials with approximately 22 patient-years of
696 exposure, is included below.

697 The conditions and duration of treatment with olanzapine varied greatly and included (in
698 overlapping categories) open-label and double-blind phases of studies, inpatients and outpatients,
699 fixed-dose and dose-titration studies, and short-term or longer-term exposure. Adverse reactions
700 were assessed by collecting adverse events, results of physical examinations, vital signs, weights,
701 laboratory analytes, ECGs, chest x-rays, and results of ophthalmologic examinations.

702 Certain portions of the discussion below relating to objective or numeric safety parameters,
703 namely, dose-dependent adverse events, vital sign changes, weight gain, laboratory changes, and
704 ECG changes are derived from studies in patients with schizophrenia and have not been
705 duplicated for bipolar mania or agitation. However, this information is also generally applicable
706 to bipolar mania and agitation.

707 Adverse events during exposure were obtained by spontaneous report and recorded by clinical
708 investigators using terminology of their own choosing. Consequently, it is not possible to provide
709 a meaningful estimate of the proportion of individuals experiencing adverse events without first
710 grouping similar types of events into a smaller number of standardized event categories. In the
711 tables and tabulations that follow, standard COSTART dictionary terminology has been used
712 initially to classify reported adverse events.

713 The stated frequencies of adverse events represent the proportion of individuals who
714 experienced, at least once, a treatment-emergent adverse event of the type listed. An event was
715 considered treatment emergent if it occurred for the first time or worsened while receiving
716 therapy following baseline evaluation. The reported events do not include those event terms that

717 were so general as to be uninformative. Events listed elsewhere in labeling may not be repeated
 718 below. It is important to emphasize that, although the events occurred during treatment with
 719 olanzapine, they were not necessarily caused by it. The entire label should be read to gain a
 720 complete understanding of the safety profile of olanzapine.

721 The prescriber should be aware that the figures in the tables and tabulations cannot be used to
 722 predict the incidence of side effects in the course of usual medical practice where patient
 723 characteristics and other factors differ from those that prevailed in the clinical trials. Similarly,
 724 the cited frequencies cannot be compared with figures obtained from other clinical investigations
 725 involving different treatments, uses, and investigators. The cited figures, however, do provide the
 726 prescribing physician with some basis for estimating the relative contribution of drug and
 727 nondrug factors to the adverse event incidence in the population studied.

728 **Incidence of Adverse Events in Short-Term, Placebo-Controlled and Combination** 729 **Trials**

730 The following findings are based on premarketing trials of (1) oral olanzapine for
 731 schizophrenia, bipolar mania, a subsequent trial of patients having various psychiatric symptoms
 732 in association with Alzheimer's disease, and premarketing combination trials, and
 733 (2) intramuscular olanzapine for injection in agitated patients with schizophrenia or bipolar
 734 mania.

735 **Adverse Events Associated with Discontinuation of Treatment in Short-Term, Placebo-** 736 **Controlled Trials**

737 Schizophrenia — Overall, there was no difference in the incidence of discontinuation due to
 738 adverse events (5% for oral olanzapine vs 6% for placebo). However, discontinuations due to
 739 increases in SGPT were considered to be drug related (2% for oral olanzapine vs 0% for placebo)
 740 (*see* PRECAUTIONS).

741 Bipolar Mania Monotherapy — Overall, there was no difference in the incidence of
 742 discontinuation due to adverse events (2% for oral olanzapine vs 2% for placebo).

743 Agitation — Overall, there was no difference in the incidence of discontinuation due to adverse
 744 events (0.4% for intramuscular olanzapine for injection vs 0% for placebo).

745 **Adverse Events Associated with Discontinuation of Treatment in Short-Term** 746 **Combination Trials**

747 Bipolar Mania Combination Therapy — In a study of patients who were already tolerating
 748 either lithium or valproate as monotherapy, discontinuation rates due to adverse events were
 749 11% for the combination of oral olanzapine with lithium or valproate compared to 2% for
 750 patients who remained on lithium or valproate monotherapy. Discontinuations with the
 751 combination of oral olanzapine and lithium or valproate that occurred in more than 1 patient
 752 were: somnolence (3%), weight gain (1%), and peripheral edema (1%).

753 **Commonly Observed Adverse Events in Short-Term, Placebo-Controlled Trials**

754 The most commonly observed adverse events associated with the use of oral olanzapine
 755 (incidence of 5% or greater) and not observed at an equivalent incidence among placebo-treated
 756 patients (olanzapine incidence at least twice that for placebo) were:

757

Common Treatment-Emergent Adverse Events Associated with the Use of Oral Olanzapine in 6-Week Trials — SCHIZOPHRENIA		
Adverse Event	Percentage of Patients Reporting Event	
	Olanzapine (N=248)	Placebo (N=118)
Postural hypotension	5	2

Constipation	9	3
Weight gain	6	1
Dizziness	11	4
Personality disorder ¹	8	4
Akathisia	5	1

¹ Personality disorder is the COSTART term for designating non-aggressive objectionable behavior.

758
759

Common Treatment-Emergent Adverse Events Associated with the Use of Oral Olanzapine in 3-Week and 4-Week Trials — BIPOLAR MANIA		
Adverse Event	Percentage of Patients Reporting Event	
	Olanzapine (N=125)	Placebo (N=129)
Asthenia	15	6
Dry mouth	22	7
Constipation	11	5
Dyspepsia	11	5
Increased appetite	6	3
Somnolence	35	13
Dizziness	18	6
Tremor	6	3

760

761 There was one adverse event (somnolence) observed at an incidence of 5% or greater among
762 intramuscular olanzapine for injection-treated patients and not observed at an equivalent
763 incidence among placebo-treated patients (olanzapine incidence at least twice that for placebo)
764 during the placebo-controlled premarketing studies. The incidence of somnolence during the
765 24 hour IM treatment period in clinical trials in agitated patients with schizophrenia or bipolar
766 mania was 6% for intramuscular olanzapine for injection and 3% for placebo.

767 Adverse Events Occurring at an Incidence of 2% or More Among Oral Olanzapine-
768 Treated Patients in Short-Term, Placebo-Controlled Trials

769 Table 1 enumerates the incidence, rounded to the nearest percent, of treatment-emergent
770 adverse events that occurred in 2% or more of patients treated with oral olanzapine (doses
771 ≥ 2.5 mg/day) and with incidence greater than placebo who participated in the acute phase of
772 placebo-controlled trials.

773

Table 1
Treatment-Emergent Adverse Events:
Incidence in Short-Term, Placebo-Controlled Clinical Trials¹
with Oral Olanzapine

Body System/Adverse Event	Percentage of Patients Reporting Event	
	Olanzapine (N=532)	Placebo (N=294)

Urinary tract infection	2	1

774 ¹ Events reported by at least 2% of patients treated with olanzapine, except the following events which had an
775 incidence equal to or less than placebo: abdominal pain, agitation, anorexia, anxiety, apathy, confusion, depression,
776 diarrhea, dysmenorrhea², hallucinations, headache, hostility, hyperkinesia, myalgia, nausea, nervousness, paranoid
777 reaction, personality disorder³, rash, thinking abnormal, weight loss.

778 ² Denominator used was for females only (olanzapine, N=201; placebo, N=114).

779 ³ Personality disorder is the COSTART term for designating non-aggressive objectionable behavior.

780

781 Commonly Observed Adverse Events in Short-Term Combination Trials

782 In the bipolar mania combination placebo-controlled trials, the most commonly observed
 783 adverse events associated with the combination of olanzapine and lithium or valproate (incidence
 784 of $\geq 5\%$ and at least twice placebo) were:

785

Common Treatment-Emergent Adverse Events Associated with the Use of Oral Olanzapine in 6-Week Combination Trials — BIPOLAR MANIA		
Adverse Event	Percentage of Patients Reporting Event	
	Olanzapine with lithium or valproate (N=229)	Placebo with lithium or valproate (N=115)
Dry mouth	32	9

794 ¹ Events reported by at least 2% of patients treated with olanzapine, except the following events which had an
795 incidence equal to or less than placebo: abdominal pain, abnormal dreams, abnormal ejaculation, agitation,
796 akathisia, anorexia, anxiety, arthralgia, cough increased, diarrhea, dyspepsia, emotional lability, fever, flatulence,
797 flu syndrome, headache, hostility, insomnia, libido decreased, libido increased, menstrual disorder², myalgia,
798 nausea, nervousness, pain, paranoid reaction, personality disorder, rash, rhinitis, sleep disorder, thinking abnormal,
799 vomiting.

800 ² Denominator used was for females only (olanzapine, N=128; placebo, N=51).
801

802 For specific information about the adverse reactions observed with lithium or valproate, refer
803 to the ADVERSE REACTIONS section of the package inserts for these other products.

804 Adverse Events Occurring at an Incidence of 1% or More Among Intramuscular
805 Olanzapine for Injection-Treated Patients in Short-Term, Placebo-Controlled Trials

806 Table 3 enumerates the incidence, rounded to the nearest percent, of treatment-emergent
807 adverse events that occurred in 1% or more of patients treated with intramuscular olanzapine for

808 injection (dose range of 2.5-10 mg/injection) and with incidence greater than placebo who
 809 participated in the short-term, placebo-controlled trials in agitated patients with schizophrenia or
 810 bipolar mania.
 811

Table 3
Treatment-Emergent Adverse Events:
Incidence in Short-Term (24 Hour), Placebo-Controlled Clinical Trials
with Intramuscular Olanzapine for Injection
in Agitated Patients with Schizophrenia or Bipolar Mania¹

Body System/Adverse Event	Percentage of Patients Reporting Event	
	Olanzapine (N=415)	Placebo (N=150)
Body as a Whole		
Asthenia	2	1
Cardiovascular System		
Hypotension	2	0
Postural hypotension	1	0
Nervous System		
Somnolence	6	3
Dizziness	4	2
Tremor	1	0

812 ¹ Events reported by at least 1% of patients treated with olanzapine for injection, except the following events which
 813 had an incidence equal to or less than placebo: agitation, anxiety, dry mouth, headache, hypertension, insomnia,
 814 nervousness.
 815

816 Additional Findings Observed in Clinical Trials

817 The following findings are based on clinical trials.

818 Dose Dependency of Adverse Events in Short-Term, Placebo-Controlled Trials

819 Extrapyramidal Symptoms — The following table enumerates the percentage of patients with
 820 treatment-emergent extrapyramidal symptoms as assessed by categorical analyses of formal
 821 rating scales during acute therapy in a controlled clinical trial comparing oral olanzapine at
 822 3 fixed doses with placebo in the treatment of schizophrenia.
 823

TREATMENT-EMERGENT EXTRAPYRAMIDAL SYMPTOMS ASSESSED BY RATING
 SCALES INCIDENCE IN A FIXED DOSAGE RANGE, PLACEBO-CONTROLLED
 CLINICAL TRIAL OF ORAL OLANZAPINE IN SCHIZOPHRENIA — ACUTE PHASE*

	Percentage of Patients Reporting Event			
	Placebo	Olanzapine 5 ± 2.5 mg/day	Olanzapine 10 ± 2.5 mg/day	Olanzapine 15 ± 2.5 mg/day
Parkinsonism ¹	15	14	12	14
Akathisia ²	23	16	19	27

824 * No statistically significant differences.

825 ¹ Percentage of patients with a Simpson-Angus Scale total score >3.

826 ² Percentage of patients with a Barnes Akathisia Scale global score ≥2.
 827

828 The following table enumerates the percentage of patients with treatment-emergent
 829 extrapyramidal symptoms as assessed by spontaneously reported adverse events during acute

830 therapy in the same controlled clinical trial comparing olanzapine at 3 fixed doses with placebo
831 in the treatment of schizophrenia.
832

TREATMENT-EMERGENT EXTRAPYRAMIDAL SYMPTOMS ASSESSED BY ADVERSE
EVENTS INCIDENCE IN A FIXED DOSAGE RANGE, PLACEBO-CONTROLLED
CLINICAL TRIAL OF ORAL OLANZAPINE IN SCHIZOPHRENIA — ACUTE PHASE

	Percentage of Patients Reporting Event			
	Placebo (N=68)	Olanzapine 5 ± 2.5 mg/day (N=65)	Olanzapine 10 ± 2.5 mg/day (N=64)	Olanzapine 15 ± 2.5 mg/day (N=69)
Dystonic events ¹	1	3	2	3
Parkinsonism events ²	10	8	14	20

Dyskinetic events ⁴	4	0	2	1
Residual events ⁵	1	2	5	1
Any extrapyramidal event	16	15	25	32*

833 * Statistically significantly different from placebo.

834 ¹ Patients with the following COSTART terms were counted in this category: dystonia, generalized spasm, neck
835 rigidity, oculogyric crisis, opisthotonos, torticollis.

836 ² Patients with the following COSTART terms were counted in this category: akinesia, cogwheel rigidity,
837 extrapyramidal syndrome, hypertonia, hypokinesia, masked facies, tremor.

838 ³ Patients with the following COSTART terms were counted in this category: akathisia, hyperkinesia.

839 ⁴ Patients with the following COSTART terms were counted in this category: buccoglossal syndrome,
840 choreoathetosis, dyskinesia, tardive dyskinesia.

841 ⁵ Patients with the following COSTART terms were counted in this category: movement disorder, myoclonus,
842 twitching.
843

844 The following table enumerates the percentage of patients with treatment-emergent
845 extrapyramidal symptoms as assessed by categorical analyses of formal rating scales during
846 controlled clinical trials comparing fixed doses of intramuscular olanzapine for injection with
847 placebo in agitation. Patients in each dose group could receive up to three injections during the
848 trials (*see* CLINICAL PHARMACOLOGY). Patient assessments were conducted during the
849 24 hours following the initial dose of intramuscular olanzapine for injection. There were no
850 statistically significant differences from placebo.
851

873 Other Adverse Events — The following table addresses dose relatedness for other adverse
 874 events using data from a schizophrenia trial involving fixed dosage ranges of oral olanzapine. It
 875 enumerates the percentage of patients with treatment-emergent adverse events for the
 876 three fixed-dose range groups and placebo. The data were analyzed using the Cochran-Armitage
 877 test, excluding the placebo group, and the table includes only those adverse events for which
 878 there was a statistically significant trend.
 879

Adverse Event	Percentage of Patients Reporting Event			
	Placebo (N=68)	Olanzapine 5 ± 2.5 mg/day (N=65)	Olanzapine 10 ± 2.5 mg/day (N=64)	Olanzapine 15 ± 2.5 mg/day (N=69)
Asthenia	15	8	9	20
Dry mouth	4	3	5	13
Nausea	9	0	2	9
Somnolence	16	20	30	39
Tremor	3	0	5	7

880

881 *Vital Sign Changes* — Oral olanzapine was associated with orthostatic hypotension and
882 tachycardia in clinical trials. Intramuscular olanzapine for injection was associated with
883 bradycardia, hypotension, and tachycardia in clinical trials (*see* PRECAUTIONS).

884 *Weight Gain* — In placebo-controlled, 6-week studies, weight gain was reported in 5.6% of
885 olanzapine patients compared to 0.8% of placebo patients. Olanzapine patients gained an average
886 of 2.8 kg, compared to an average 0.4 kg weight loss in placebo patients; 29% of olanzapine
887 patients gained greater than 7% of their baseline weight, compared to 3% of placebo patients. A
888 categorization of patients at baseline on the basis of body mass index (BMI) revealed a
889 significantly greater effect in patients with low BMI compared to normal or overweight patients;
890 nevertheless, weight gain was greater in all 3 olanzapine groups compared to the placebo group.
891 During long-term continuation therapy with olanzapine (238 median days of exposure), 56% of
892 olanzapine patients met the criterion for having gained greater than 7% of their baseline weight.
893 Average weight gain during long-term therapy was 5.4 kg.

894 *Laboratory Changes* — An assessment of the premarketing experience for olanzapine revealed
895 an association with asymptomatic increases in SGPT, SGOT, and GGT (*see* PRECAUTIONS).
896 Olanzapine administration was also associated with increases in serum prolactin (*see*
897 PRECAUTIONS), with an asymptomatic elevation of the eosinophil count in 0.3% of patients,
898 and with an increase in CPK.

899 Given the concern about neutropenia associated with other psychotropic compounds and the
900 finding of leukopenia associated with the administration of olanzapine in several animal models
901 (*see* ANIMAL TOXICOLOGY), careful attention was given to examination of hematologic
902 parameters in premarketing studies with olanzapine. There was no indication of a risk of
903 clinically significant neutropenia associated with olanzapine treatment in the premarketing
904 database for this drug.

905 In clinical trials among olanzapine-treated patients with random triglyceride levels of
906 <150 mg/dL at baseline (N=659), 0.5% of patients experienced triglyceride levels of ≥500 mg/dL
907 anytime during the trials. In these same trials, olanzapine-treated patients (N=1185) had a mean
908 increase of 20 mg/dL in triglycerides from a mean baseline value of 175 mg/dL.

909 In placebo-controlled trials, olanzapine-treated patients with random cholesterol levels of
910 <200 mg/dL at baseline (N=1034) experienced cholesterol levels of ≥240 mg/dL anytime during
911 the trials more often than placebo-treated patients (N=602) (3.6% vs 2.2%, respectively). In these
912 same trials, olanzapine-treated patients (N=2528) had a mean increase of 0.4 mg/dL in
913 cholesterol from a mean baseline value of 203 mg/dL, which was significantly different
914 compared to placebo-treated patients (N=1415) with a mean decrease of 4.6 mg/dL from a mean
915 baseline value of 203 mg/dL.

916 *ECG Changes* — Between-group comparisons for pooled placebo-controlled trials revealed no
917 statistically significant olanzapine/placebo differences in the proportions of patients experiencing
918 potentially important changes in ECG parameters, including QT, QTc, and PR intervals.
919 Olanzapine use was associated with a mean increase in heart rate of 2.4 beats per minute
920 compared to no change among placebo patients. This slight tendency to tachycardia may be
921 related to olanzapine's potential for inducing orthostatic changes (*see* PRECAUTIONS).

922 **Other Adverse Events Observed During the Clinical Trial Evaluation of** 923 **Olanzapine**

924 Following is a list of terms that reflect treatment-emergent adverse events reported by patients
925 treated with oral olanzapine (at multiple doses ≥1 mg/day) in clinical trials (8661 patients,
926 4165 patient-years of exposure). This listing may not include those events already listed in
927 previous tables or elsewhere in labeling, those events for which a drug cause was remote, those
928 event terms which were so general as to be uninformative, and those events reported only once or
929 twice which did not have a substantial probability of being acutely life-threatening.

930 Events are further categorized by body system and listed in order of decreasing frequency
 931 according to the following definitions: frequent adverse events are those occurring in at least
 932 1/100 patients (only those not already listed in the tabulated results from placebo-controlled trials
 933 appear in this listing); infrequent adverse events are those occurring in 1/100 to 1/1000 patients;
 934 rare events are those occurring in fewer than 1/1000 patients.

935 **Body as a Whole** — *Frequent*: dental pain and flu syndrome; *Infrequent*: abdomen enlarged,
 936 chills, face edema, intentional injury, malaise, moniliasis, neck pain, neck rigidity, pelvic pain,
 937 photosensitivity reaction, and suicide attempt; *Rare*: chills and fever, hangover effect, and
 938 sudden death.

939 **Cardiovascular System** — *Frequent*: hypotension; *Infrequent*: atrial fibrillation, bradycardia,
 940 cerebrovascular accident, congestive heart failure, heart arrest, hemorrhage, migraine, pallor,
 941 palpitation, vasodilatation, and ventricular extrasystoles; *Rare*: arteritis, heart failure, and
 942 pulmonary embolus.

943 **Digestive System** — *Frequent*: flatulence, increased salivation, and thirst;
 944 *Infrequent*: dysphagia, esophagitis, fecal impaction, fecal incontinence, gastritis, gastroenteritis,
 945 gingivitis, hepatitis, melena, mouth ulceration, nausea and vomiting, oral moniliasis, periodontal
 946 abscess, rectal hemorrhage, stomatitis, tongue edema, and tooth caries; *Rare*: aphthous
 947 stomatitis, enteritis, eructation, esophageal ulcer, glossitis, ileus, intestinal obstruction, liver fatty
 948 deposit, and tongue discoloration.

949 **Endocrine System** — *Infrequent*: diabetes mellitus; *Rare*: diabetic acidosis and goiter.

950 **Hemic and Lymphatic System** — *Infrequent*: anemia, cyanosis, leukocytosis, leukopenia,
 951 lymphadenopathy, and thrombocytopenia; *Rare*: normocytic anemia and thrombocythemia.

952 **Metabolic and Nutritional Disorders** — *Infrequent*: acidosis, alkaline phosphatase increased,
 953 bilirubinemia, dehydration, hypercholesteremia, hyperglycemia, hyperlipemia, hyperuricemia,
 954 hypoglycemia, hypokalemia, hyponatremia, lower extremity edema, and upper extremity edema;
 955 *Rare*: gout, hyperkalemia, hypernatremia, hypoproteinemia, ketosis, and water intoxication.

956 **Musculoskeletal System** — *Frequent*: joint stiffness and twitching; *Infrequent*: arthritis,
 957 arthrosis, leg cramps, and myasthenia; *Rare*: bone pain, bursitis, myopathy, osteoporosis, and
 958 rheumatoid arthritis.

959 **Nervous System** — *Frequent*: abnormal dreams, amnesia, delusions, emotional lability,
 960 euphoria, manic reaction, paresthesia, and schizophrenic reaction; *Infrequent*: akinesia, alcohol
 961 misuse, antisocial reaction, ataxia, CNS stimulation, cogwheel rigidity, delirium, dementia,
 962 depersonalization, dysarthria, facial paralysis, hypesthesia, hypokinesia, hypotonia,
 963 incoordination, libido decreased, libido increased, obsessive compulsive symptoms, phobias,
 964 somatization, stimulant misuse, stupor, stuttering, tardive dyskinesia, vertigo, and withdrawal
 965 syndrome; *Rare*: circumoral paresthesia, coma, encephalopathy, neuralgia, neuropathy,
 966 nystagmus, paralysis, subarachnoid hemorrhage, and tobacco misuse.

967 **Respiratory System** — *Frequent*: dyspnea; *Infrequent*: apnea, asthma, epistaxis, hemoptysis,
 968 hyperventilation, hypoxia, laryngitis, and voice alteration; *Rare*: atelectasis, hiccup,
 969 hypoventilation, lung edema, and stridor.

970 **Skin and Appendages** — *Frequent*: sweating; *Infrequent*: alopecia, contact dermatitis, dry
 971 skin, eczema, maculopapular rash, pruritus, seborrhea, skin discoloration, skin ulcer, urticaria,
 972 and vesiculobullous rash; *Rare*: hirsutism and pustular rash.

973 **Special Senses** — *Frequent*: conjunctivitis; *Infrequent*: abnormality of accommodation,
 974 blepharitis, cataract, deafness, diplopia, dry eyes, ear pain, eye hemorrhage, eye inflammation,
 975 eye pain, ocular muscle abnormality, taste perversion, and tinnitus; *Rare*: corneal lesion,
 976 glaucoma, keratoconjunctivitis, macular hypopigmentation, miosis, mydriasis, and pigment
 977 deposits lens.

978 **Urogenital System** — *Frequent*: vaginitis*; *Infrequent*: abnormal ejaculation*, amenorrhea*,
 979 breast pain, cystitis, decreased menstruation*, dysuria, female lactation*, glycosuria,
 980 gynecomastia, hematuria, impotence*, increased menstruation*, menorrhagia*, metrorrhagia*,
 981 polyuria, premenstrual syndrome*, pyuria, urinary frequency, urinary retention, urinary urgency,
 982 urination impaired, uterine fibroids enlarged*, and vaginal hemorrhage*; *Rare*: albuminuria,
 983 breast enlargement, mastitis, and oliguria.

984 * Adjusted for gender.

985

986 Following is a list of terms that reflect treatment-emergent adverse events reported by patients
 987 treated with intramuscular olanzapine for injection (at one or more doses ≥ 2.5 mg/injection) in
 988 clinical trials (722 patients). This listing may not include those events already listed in previous
 989 tables or elsewhere in labeling, those events for which a drug cause was remote, those event
 990 terms which were so general as to be uninformative, and those events reported only once which
 991 did not have a substantial probability of being acutely life-threatening.

992 Events are further categorized by body system and listed in order of decreasing frequency
 993 according to the following definitions: frequent adverse events are those occurring in at least
 994 1/100 patients (only those not already listed in the tabulated results from placebo-controlled trials
 995 appear in this listing); infrequent adverse events are those occurring in 1/100 to 1/1000 patients.

996 **Body as a Whole** — *Frequent*: injection site pain; *Infrequent*: abdominal pain and fever.

997 **Cardiovascular System** — *Infrequent*: AV block, heart block, and syncope.

998 **Digestive System** — *Infrequent*: diarrhea and nausea.

999 **Hemic and Lymphatic System** — *Infrequent*: anemia.

1000 **Metabolic and Nutritional Disorders** — *Infrequent*: creatine phosphokinase increased,
 1001 dehydration, and hyperkalemia.

1002 **Musculoskeletal System** — *Infrequent*: twitching.

1003 **Nervous System** — *Infrequent*: abnormal gait, akathisia, articulation impairment, confusion,
 1004 and emotional lability.

1005 **Skin and Appendages** — *Infrequent*: sweating.

1006 **Postintroduction Reports**

1007 Adverse events reported since market introduction that were temporally (but not necessarily
 1008 causally) related to ZYPREXA therapy include the following: allergic reaction
 1009 (e.g., anaphylactoid reaction, angioedema, pruritus or urticaria), diabetic coma, pancreatitis,
 1010 priapism, rhabdomyolysis, and venous thromboembolic events (including pulmonary embolism
 1011 and deep venous thrombosis). Random cholesterol levels of ≥ 240 mg/dL and random triglyceride
 1012 levels of ≥ 1000 mg/dL have been rarely reported.

1013 **DRUG ABUSE AND DEPENDENCE**

1014 **Controlled Substance Class**

1015 Olanzapine is not a controlled substance.

1016 **Physical and Psychological Dependence**

1017 In studies prospectively designed to assess abuse and dependence potential, olanzapine was
 1018 shown to have acute depressive CNS effects but little or no potential of abuse or physical
 1019 dependence in rats administered oral doses up to 15 times the maximum recommended human
 1020 daily oral dose (20 mg) and rhesus monkeys administered oral doses up to 8 times the maximum
 1021 recommended human daily oral dose on a mg/m^2 basis.

1022 Olanzapine has not been systematically studied in humans for its potential for abuse, tolerance,
 1023 or physical dependence. While the clinical trials did not reveal any tendency for any drug-seeking
 1024 behavior, these observations were not systematic, and it is not possible to predict on the basis of

1025 this limited experience the extent to which a CNS-active drug will be misused, diverted, and/or
 1026 abused once marketed. Consequently, patients should be evaluated carefully for a history of drug
 1027 abuse, and such patients should be observed closely for signs of misuse or abuse of olanzapine
 1028 (e.g., development of tolerance, increases in dose, drug-seeking behavior).

1029

OVERDOSAGE

1030 Human Experience

1031 In premarketing trials involving more than 3100 patients and/or normal subjects, accidental or
 1032 intentional acute overdosage of olanzapine was identified in 67 patients. In the patient taking the
 1033 largest identified amount, 300 mg, the only symptoms reported were drowsiness and slurred
 1034 speech. In the limited number of patients who were evaluated in hospitals, including the patient
 1035 taking 300 mg, there were no observations indicating an adverse change in laboratory analytes or
 1036 ECG. Vital signs were usually within normal limits following overdoses.

1037 In postmarketing reports of overdose with olanzapine alone, symptoms have been reported in
 1038 the majority of cases. In symptomatic patients, symptoms with $\geq 10\%$ incidence included
 1039 agitation/aggressiveness, dysarthria, tachycardia, various extrapyramidal symptoms, and reduced
 1040 level of consciousness ranging from sedation to coma. Among less commonly reported
 1041 symptoms were the following potentially medically serious events: aspiration, cardiopulmonary
 1042 arrest, cardiac arrhythmias (such as supraventricular tachycardia and one patient experiencing
 1043 sinus pause with spontaneous resumption of normal rhythm), delirium, possible neuroleptic
 1044 malignant syndrome, respiratory depression/arrest, convulsion, hypertension, and hypotension.
 1045 Eli Lilly and Company has received reports of fatality in association with overdose of olanzapine
 1046 alone. In one case of death, the amount of acutely ingested olanzapine was reported to be
 1047 possibly as low as 450 mg; however, in another case, a patient was reported to survive an acute
 1048 olanzapine ingestion of 1500 mg.

1049 Overdosage Management

1050 The possibility of multiple drug involvement should be considered. In case of acute
 1051 overdosage, establish and maintain an airway and ensure adequate oxygenation and ventilation,
 1052 which may include intubation. Gastric lavage (after intubation, if patient is unconscious) and
 1053 administration of activated charcoal together with a laxative should be considered. The
 1054 possibility of obtundation, seizures, or dystonic reaction of the head and neck following overdose
 1055 may create a risk of aspiration with induced emesis. Cardiovascular monitoring should
 1056 commence immediately and should include continuous electrocardiographic monitoring to detect
 1057 possible arrhythmias.

1058 There is no specific antidote to olanzapine. Therefore, appropriate supportive measures should
 1059 be initiated. Hypotension and circulatory collapse should be treated with appropriate measures
 1060 such as intravenous fluids and/or sympathomimetic agents. (Do not use epinephrine, dopamine,
 1061 or other sympathomimetics with beta-agonist activity, since beta stimulation may worsen
 1062 hypotension in the setting of olanzapine-induced alpha blockade.) Close medical supervision and
 1063 monitoring should continue until the patient recovers.

1064

DOSAGE AND ADMINISTRATION

1065 Schizophrenia

1066 Usual Dose — Oral olanzapine should be administered on a once-a-day schedule without
 1067 regard to meals, generally beginning with 5 to 10 mg initially, with a target dose of 10 mg/day
 1068 within several days. Further dosage adjustments, if indicated, should generally occur at intervals
 1069 of not less than 1 week, since steady state for olanzapine would not be achieved for
 1070 approximately 1 week in the typical patient. When dosage adjustments are necessary, dose
 1071 increments/decrements of 5 mg QD are recommended.

1072 Efficacy in schizophrenia was demonstrated in a dose range of 10 to 15 mg/day in clinical
1073 trials. However, doses above 10 mg/day were not demonstrated to be more efficacious than the
1074 10 mg/day dose. An increase to a dose greater than the target dose of 10 mg/day (i.e., to a dose of
1075 15 mg/day or greater) is recommended only after clinical assessment. The safety of doses above
1076 20 mg/day has not been evaluated in clinical trials.

1077 Dosing in Special Populations — The recommended starting dose is 5 mg in patients who are
1078 debilitated, who have a predisposition to hypotensive reactions, who otherwise exhibit a
1079 combination of factors that may result in slower metabolism of olanzapine (e.g., nonsmoking
1080 female patients ≥ 65 years of age), or who may be more pharmacodynamically sensitive to
1081 olanzapine (*see* CLINICAL PHARMACOLOGY; also *see* Use in Patients with Concomitant
1082 Illness and Drug Interactions *under* PRECAUTIONS). When indicated, dose escalation should
1083 be performed with caution in these patients.

1084 Maintenance Treatment — While there is no body of evidence available to answer the question
1085 of how long the patient treated with olanzapine should remain on it, the effectiveness of oral
1086 olanzapine, 10 mg/day to 20 mg/day, in maintaining treatment response in schizophrenic patients
1087 who had been stable on ZYPREXA for approximately 8 weeks and were then followed for a
1088 period of up to 8 months has been demonstrated in a placebo-controlled trial (*see* CLINICAL
1089 PHARMACOLOGY). Patients should be periodically reassessed to determine the need for
1090 maintenance treatment with appropriate dose.

1091 **Bipolar Disorder**

1092 Usual Monotherapy Dose — Oral olanzapine should be administered on a once-a-day schedule
1093 without regard to meals, generally beginning with 10 or 15 mg. Dosage adjustments, if indicated,
1094 should generally occur at intervals of not less than 24 hours, reflecting the procedures in the
1095 placebo-controlled trials. When dosage adjustments are necessary, dose increments/decrements
1096 of 5 mg QD are recommended.

1097 Short-term (3-4 weeks) antimanic efficacy was demonstrated in a dose range of 5 mg to
1098 20 mg/day in clinical trials. The safety of doses above 20 mg/day has not been evaluated in
1099 clinical trials.

1100 Maintenance Monotherapy — The benefit of maintaining bipolar patients on monotherapy with
1101 oral ZYPREXA at a dose of 5 to 20 mg/day, after achieving a responder status for an average
1102 duration of two weeks, was demonstrated in a controlled trial (*see* Clinical Efficacy Data *under*
1103 CLINICAL PHARMACOLOGY). The physician who elects to use ZYPREXA for extended
1104 periods should periodically re-evaluate the long-term usefulness of the drug for the individual
1105 patient.

1106 Bipolar Mania Usual Dose in Combination with Lithium or Valproate — When administered
1107 in combination with lithium or valproate, oral olanzapine dosing should generally begin with
1108 10 mg once-a-day without regard to meals.

1109 Short-term (6 weeks) antimanic efficacy was demonstrated in a dose range of 5 mg to
1110 20 mg/day in clinical trials. The safety of doses above 20 mg/day has not been evaluated in
1111 clinical trials.

1112 Dosing in Special Populations — *See* Dosing in Special Populations *under* DOSAGE AND
1113 ADMINISTRATION, Schizophrenia.

1114 *Administration of ZYPREXA ZYDIS (olanzapine orally disintegrating tablets)*

1115 After opening sachet, peel back foil on blister. Do not push tablet through foil. Immediately
1116 upon opening the blister, using dry hands, remove tablet and place entire ZYPREXA ZYDIS in
1117 the mouth. Tablet disintegration occurs rapidly in saliva so it can be easily swallowed with or
1118 without liquid.

1119 **Agitation Associated with Schizophrenia and Bipolar I Mania**

1120 Usual Dose for Agitated Patients with Schizophrenia or Bipolar Mania — The efficacy of
 1121 intramuscular olanzapine for injection in controlling agitation in these disorders was
 1122 demonstrated in a dose range of 2.5 mg to 10 mg. The recommended dose in these patients is
 1123 10 mg. A lower dose of 5 or 7.5 mg may be considered when clinical factors warrant (*see*
 1124 CLINICAL PHARMACOLOGY). If agitation warranting additional intramuscular doses persists
 1125 following the initial dose, subsequent doses up to 10 mg may be given. However, the efficacy of
 1126 repeated doses of intramuscular olanzapine for injection in agitated patients has not been
 1127 systematically evaluated in controlled clinical trials. Also, the safety of total daily doses greater
 1128 than 30 mg, or 10 mg injections given more frequently than 2 hours after the initial dose, and
 1129 4 hours after the second dose have not been evaluated in clinical trials. Maximal dosing of
 1130 intramuscular olanzapine (e.g., three doses of 10 mg administered 2-4 hours apart) may be
 1131 associated with a substantial occurrence of significant orthostatic hypotension (*see*
 1132 PRECAUTIONS, Hemodynamic Effects). Thus, it is recommended that patients requiring
 1133 subsequent intramuscular injections be assessed for orthostatic hypotension prior to the
 1134 administration of any subsequent doses of intramuscular olanzapine for injection. The
 1135 administration of an additional dose to a patient with a clinically significant postural change in
 1136 systolic blood pressure is not recommended.

1137 If ongoing olanzapine therapy is clinically indicated, oral olanzapine may be initiated in a range
 1138 of 5-20 mg/day as soon as clinically appropriate (*see* Schizophrenia or Bipolar Disorder *under*
 1139 DOSAGE AND ADMINISTRATION).

1140 Intramuscular Dosing in Special Populations — A dose of 5 mg per injection should be
 1141 considered for geriatric patients or when other clinical factors warrant. A lower dose of 2.5 mg
 1142 per injection should be considered for patients who otherwise might be debilitated, be
 1143 predisposed to hypotensive reactions, or be more pharmacodynamically sensitive to olanzapine
 1144 (*see* CLINICAL PHARMACOLOGY; also *see* Use in Patients with Concomitant Illness and
 1145 Drug Interactions *under* PRECAUTIONS).

1146 *Administration of ZYPREXA IntraMuscular*

1147 ZYPREXA IntraMuscular is intended for intramuscular use only. Do not administer
 1148 intravenously or subcutaneously. Inject slowly, deep into the muscle mass.

1149 Parenteral drug products should be inspected visually for particulate matter and discoloration
 1150 prior to administration, whenever solution and container permit.

1151 *Directions for preparation of ZYPREXA IntraMuscular with Sterile Water for Injection*

1152 Dissolve the contents of the vial using 2.1 mL of Sterile Water for Injection to provide a
 1153 solution containing approximately 5 mg/mL of olanzapine. The resulting solution should appear
 1154 clear and yellow. ZYPREXA IntraMuscular reconstituted with Sterile Water for Injection should
 1155 be used immediately (within 1 hour) after reconstitution. **Discard any unused portion.**

1156 The following table provides injection volumes for delivering various doses of intramuscular
 1157 olanzapine for injection reconstituted with Sterile Water for Injection.

1158

<u>Dose, mg Olanzapine</u>	<u>Volume of Injection, mL</u>
10	Withdraw total contents of vial
7.5	1.5
5	1
2.5	0.5

1159

1160 *Physical Incompatibility Information*

1161 ZYPREXA IntraMuscular should be reconstituted only with Sterile Water for Injection.

1162 ZYPREXA IntraMuscular should not be combined in a syringe with diazepam injection because

1163 precipitation occurs when these products are mixed. Lorazepam injection should not be used to
 1164 reconstitute ZYPREXA IntraMuscular as this combination results in a delayed reconstitution
 1165 time. ZYPREXA IntraMuscular should not be combined in a syringe with haloperidol injection
 1166 because the resulting low pH has been shown to degrade olanzapine over time.

1167 HOW SUPPLIED

1168 The ZYPREXA 2.5 mg, 5 mg, 7.5 mg, and 10 mg tablets are white, round, and imprinted in
 1169 blue ink with LILLY and tablet number. The 15 mg tablets are elliptical, blue, and debossed with
 1170 LILLY and tablet number. The 20 mg tablets are elliptical, pink, and debossed with LILLY and
 1171 tablet number. The tablets are available as follows:

	TABLET STRENGTH					
	2.5 mg	5 mg	7.5 mg	10 mg	15 mg	20 mg

NDC Codes:				
Dose Pack 30 (Child-Resistant)	NDC 0002- 4453-85	NDC 0002- 4454-85	NDC 0002- 4455-85	NDC 0002- 4456-85

1178 ZYPREXA is a registered trademark of Eli Lilly and Company.
 1179 ZYDIS is a registered trademark of Cardinal Health, Inc. or one of its subsidiaries.
 1180 *ZYPREXA ZYDIS (olanzapine orally disintegrating tablets) is manufactured for Eli Lilly and
 1181 Company by Cardinal Health, United Kingdom, SN5 8RU.
 1182

1183 ZYPREXA IntraMuscular is available in:

1184 NDC 0002-7597-01 (No. VL7597) – 10 mg vial (1s)
 1185
 1186

1187 Store ZYPREXA tablets, ZYPREXA ZYDIS, and ZYPREXA IntraMuscular vials (before
 1188 reconstitution) at controlled room temperature, 20° to 25°C (68° to 77°F) [see USP].

1189 Reconstituted ZYPREXA IntraMuscular may be stored at controlled room temperature,
1190 20° to 25°C (68° to 77°F) [*see* USP] for up to 1 hour if necessary. **Discard any unused portion**
1191 **of reconstituted ZYPREXA IntraMuscular.** The USP defines controlled room temperature as
1192 a temperature maintained thermostatically that encompasses the usual and customary working
1193 environment of 20° to 25°C (68° to 77°F); that results in a mean kinetic temperature calculated to
1194 be not more than 25°C; and that allows for excursions between 15° and 30°C (59° and 86°F) that
1195 are experienced in pharmacies, hospitals, and warehouses.

1196 Protect ZYPREXA tablets and ZYPREXA ZYDIS from light and moisture. Protect
1197 ZYPREXA IntraMuscular from light, do not freeze.

1198 ANIMAL TOXICOLOGY

1199 In animal studies with olanzapine, the principal hematologic findings were reversible
1200 peripheral cytopenias in individual dogs dosed at 10 mg/kg (17 times the maximum
1201 recommended human daily oral dose on a mg/m² basis), dose-related decreases in lymphocytes
1202 and neutrophils in mice, and lymphopenia in rats. A few dogs treated with 10 mg/kg developed
1203 reversible neutropenia and/or reversible hemolytic anemia between 1 and 10 months of
1204 treatment. Dose-related decreases in lymphocytes and neutrophils were seen in mice given doses
1205 of 10 mg/kg (equal to 2 times the maximum recommended human daily oral dose on a mg/m²
1206 basis) in studies of 3 months' duration. Nonspecific lymphopenia, consistent with decreased
1207 body weight gain, occurred in rats receiving 22.5 mg/kg (11 times the maximum recommended
1208 human daily oral dose on a mg/m² basis) for 3 months or 16 mg/kg (8 times the maximum
1209 recommended human daily oral dose on a mg/m² basis) for 6 or 12 months. No evidence of bone
1210 marrow cytotoxicity was found in any of the species examined. Bone marrows were
1211 normocellular or hypercellular, indicating that the reductions in circulating blood cells were
1212 probably due to peripheral (non-marrow) factors.
