

## HIGHLIGHTS OF PRESCRIBING INFORMATION

These highlights do not include all the information needed to use Cymbalta safely and effectively. See full prescribing information for Cymbalta.

**Cymbalta (duloxetine hydrochloride) Delayed-Release Capsules for Oral Use.**

Initial U.S. Approval: 2004

### WARNING: Suicidality and Antidepressants

See full prescribing information for complete boxed warning.

- Increased risk of suicidal thinking and behavior in children, adolescents, and young adults taking antidepressants for major depressive disorder (MDD) and other psychiatric disorders. Cymbalta is not approved for use in pediatric patients (5.1).

### RECENT MAJOR CHANGES

Indications and Usage, Major Depressive Disorder (1.1)	11/2007
Indications and Usage, Fibromyalgia (1.4)	06/2008
Dosage and Administration, Fibromyalgia (2.1)	06/2008
Dosage and Administration, Maintenance/Continuation/Extended Treatment (2.2)	06/2008
Warnings and Precautions, Hepatotoxicity (5.2)	06/2008
Warnings and Precautions, Serotonin Syndrome or Neuroleptic Malignant Syndrome (NMS)-like Reactions (5.4)	01/2009
Warnings and Precautions, Abnormal Bleeding (5.5), Hyponatremia (5.11), Urinary Retention and Hesitation (5.13)	11/2007
Warnings and Precautions, Discontinuation of Treatment with Cymbalta (5.6)	10/2007

### INDICATIONS AND USAGE

Cymbalta® is a selective serotonin and norepinephrine reuptake inhibitor (SNRI) indicated for:

- Major Depressive Disorder (MDD) (1.1)
- Generalized Anxiety Disorder (GAD) (1.2)
- Diabetic Peripheral Neuropathic Pain (DPNP) (1.3)
- Fibromyalgia (FM) (1.4)

### DOSAGE AND ADMINISTRATION

- Cymbalta should generally be administered once daily without regard to meals. Cymbalta should be swallowed whole and should not be chewed or crushed, nor should the capsule be opened and its contents be sprinkled on food or mixed with liquids (2.1).

Indication	Recommended Dose
MDD (2.1, 2.2)	Acute Treatment: 40 mg/day (20 mg twice daily) to 60 mg/day (once daily or as 30 mg twice daily); Maintenance Treatment: 60 mg/day
GAD (2.1)	60 mg/day (once daily)
DPNP (2.1)	60 mg/day (once daily)
FM (2.1)	60 mg/day (once daily)

- Some patients may benefit from starting at 30 mg once daily.
- There is no evidence that doses greater than 60 mg/day confers additional benefit, while some adverse reactions were observed to be dose-dependent.
- Discontinuing Cymbalta: A gradual dose reduction is recommended.

### DOSAGE FORMS AND STRENGTHS

- 20, 30, and 60 mg capsules (3)

### CONTRAINDICATIONS

- Use of a monoamine oxidase inhibitor concomitantly or in close temporal proximity (4.1)
- Use in patients with uncontrolled narrow-angle glaucoma (4.2).

### WARNINGS AND PRECAUTIONS

- Suicidality: Monitor for clinical worsening and suicide risk (5.1).
- Hepatotoxicity: Hepatic failure, sometimes fatal, has been reported in patients treated with Cymbalta. Cymbalta should be discontinued in

patients who develop jaundice or other evidence of clinically significant liver dysfunction and should not be resumed unless another cause can be established. Cymbalta should ordinarily not be prescribed to patients with substantial alcohol use or evidence of chronic liver disease (5.2).

- Orthostatic Hypotension and Syncope: Cases have been reported with duloxetine therapy (5.3).
- Serotonin Syndrome, or Neuroleptic Malignant Syndrome (NMS)-like reactions: Serotonin syndrome or NMS-like reactions have been reported with SSRIs and SNRIs. Discontinue Cymbalta and initiate supportive treatment (5.4, 7.14).
- Abnormal Bleeding: Cymbalta may increase the risk of bleeding events. Patients should be cautioned about the risk of bleeding associated with the concomitant use of duloxetine and NSAIDs, aspirin, or other drugs that affect coagulation (5.5, 7.4).
- Discontinuation: May result in symptoms, including dizziness, nausea, headache, fatigue, paresthesia, vomiting, irritability, nightmares, insomnia, diarrhea, anxiety, hyperhidrosis, and vertigo (5.6).
- Activation of mania or hypomania has occurred (5.7).
- Seizures: Prescribe with care in patients with a history of seizure disorder (5.8).
- Blood Pressure: Monitor blood pressure prior to initiating treatment and periodically throughout treatment (5.9).
- Inhibitors of CYP1A2 or Thioridazine: Should not administer with Cymbalta (5.10).
- Hyponatremia: Cases of hyponatremia have been reported (5.11).
- Hepatic Insufficiency and Severe Renal Impairment: Should ordinarily not be administered to these patients (5.12).
- Controlled Narrow-Angle Glaucoma: Use cautiously in these patients (5.12).
- Glucose Control in Diabetes: In diabetic peripheral neuropathic pain patients, small increases in fasting blood glucose, HbA<sub>1c</sub>, and total cholesterol have been observed (5.12).
- Conditions that Slow Gastric Emptying: Use cautiously in these patients (5.12).
- Urinary Hesitation and Retention (5.13).

### ADVERSE REACTIONS

- Most common adverse reactions (≥5% and at least twice the incidence of placebo patients): nausea, dry mouth, constipation, somnolence, hyperhidrosis, and decreased appetite (6.3).

To report SUSPECTED ADVERSE REACTIONS, contact Eli Lilly and Company at 1-800-LillyRx or FDA at 1-800-FDA-1088 or [www.fda.gov/medwatch](http://www.fda.gov/medwatch).

### DRUG INTERACTIONS

- Potent inhibitors of CYP1A2 should be avoided (7.1).
- Potent inhibitors of CYP2D6 may increase duloxetine concentrations (7.2).
- Duloxetine is a moderate inhibitor of CYP2D6 (7.9).

### USE IN SPECIFIC POPULATIONS

- Pregnancy and Nursing Mothers: Use only if the potential benefit justifies the potential risk to the fetus or child (2.3, 8.1, 8.3).

See 17 for PATIENT COUNSELING INFORMATION and the FDA approved Medication Guide (17.1).

Revised: 01/2009

## FULL PRESCRIBING INFORMATION

### WARNING: SUICIDALITY AND ANTIDEPRESSANT DRUGS

Antidepressants increased the risk compared to placebo of suicidal thinking and behavior (suicidality) in children, adolescents, and young adults in short-term studies of major depressive disorder (MDD) and other psychiatric disorders. Anyone considering the use of Cymbalta or any other antidepressant in a child, adolescent, or young adult must balance this risk with the clinical need. Short-term studies did not show an increase in the risk of suicidality with antidepressants compared to placebo in adults beyond age 24; there was a reduction in risk with antidepressants compared to placebo in adults aged 65 and older. Depression and certain other psychiatric disorders are themselves associated with increases in the risk of suicide. Patients of all ages who are started on antidepressant therapy should be monitored appropriately and observed closely for clinical worsening, suicidality, or unusual changes in behavior. Families and caregivers should be advised of the need for close observation and communication with the prescriber. Cymbalta is not approved for use in pediatric patients. [see Warnings and Precautions (5.1), Use in Specific Populations (8.4), and Information for Patients (17.2).]

## 1 INDICATIONS AND USAGE

### 1.1 Major Depressive Disorder

Cymbalta is indicated for the acute and maintenance treatment of major depressive disorder (MDD) [see Clinical Studies (14.1)].

A major depressive episode (DSM-IV) implies a prominent and relatively persistent (nearly every day for at least 2 weeks) depressed or dysphoric mood that usually interferes with daily functioning, and includes at least 5 of the following 9 symptoms: depressed mood, loss of interest in usual activities, significant change in weight and/or appetite, insomnia or hypersomnia, psychomotor agitation or retardation, increased fatigue, feelings of guilt or worthlessness, slowed thinking or impaired concentration, or a suicide attempt or suicidal ideation.

### 1.2 Generalized Anxiety Disorder

Cymbalta is indicated for the acute treatment of generalized anxiety disorder (GAD) [see Clinical Studies (14.2)].

Generalized anxiety disorder is defined by the DSM-IV as excessive anxiety and worry, present more days than not, for at least 6 months. The excessive anxiety and worry must be difficult to control and must cause significant distress or impairment in normal functioning. It must be associated with at least 3 of the following 6 symptoms: restlessness or feeling keyed up or on edge, being easily fatigued, difficulty concentrating or mind going blank, irritability, muscle tension, and/or sleep disturbance.

### 1.3 Diabetic Peripheral Neuropathic Pain

Cymbalta is indicated for the management of neuropathic pain (DPNP) associated with diabetic peripheral neuropathy [see Clinical Studies (14.3)].

### 1.4 Fibromyalgia

Cymbalta is indicated for the management of fibromyalgia (FM) [see Clinical Studies (14.4)].

## 2 DOSAGE AND ADMINISTRATION

Cymbalta should be swallowed whole and should not be chewed or crushed, nor should the capsule be opened and its contents sprinkled on food or mixed with liquids. All of these might affect the enteric coating. Cymbalta should be given without regard to meals.

### 2.1 Initial Treatment

Major Depressive Disorder — Cymbalta should be administered at a total dose of 40 mg/day (given as 20 mg twice daily) to 60 mg/day (given either once daily or as 30 mg twice daily). For some patients, it may be desirable to start at 30 mg once daily for 1 week, to allow patients to adjust to the medication before increasing to 60 mg once daily. While a 120 mg/day dose was shown to be effective, there is no evidence that doses greater than 60 mg/day confer any additional benefits. The safety of doses above 120 mg/day has not been adequately evaluated [see Clinical Studies (14.1)].

Generalized Anxiety Disorder — For most patients, the recommended starting dose for Cymbalta is 60 mg administered once daily. For some patients, it may be desirable to start at 30 mg once daily for

1 week, to allow patients to adjust to the medication before increasing to 60 mg once daily. While a 120 mg once daily dose was shown to be effective, there is no evidence that doses greater than 60 mg/day confer additional benefit. Nevertheless, if a decision is made to increase the dose beyond 60 mg once daily, dose increases should be in increments of 30 mg once daily. The safety of doses above 120 mg once daily has not been adequately evaluated [see *Clinical Studies (14.2)*].

**Diabetic Peripheral Neuropathic Pain** — The recommended dose for Cymbalta is 60 mg administered once daily. There is no evidence that doses higher than 60 mg confer additional significant benefit and the higher dose is clearly less well tolerated [see *Clinical Studies (14.3)*]. For patients for whom tolerability is a concern, a lower starting dose may be considered.

Since diabetes is frequently complicated by renal disease, a lower starting dose and gradual increase in dose should be considered for patients with renal impairment [see *Clinical Pharmacology (12.3) and Dosing in Special Populations (2.3)*].

**Fibromyalgia** — The recommended dose for Cymbalta is 60 mg administered once daily. Treatment should begin at 30 mg once daily for 1 week, to allow patients to adjust to the medication before increasing to 60 mg once daily. Some patients may respond to the starting dose. There is no evidence that doses greater than 60 mg/day confer additional benefit, even in patients who do not respond to a 60 mg dose, and higher doses are associated with a higher rate of adverse reactions [see *Clinical Studies (14.4)*].

## 2.2 Maintenance/Continuation/Extended Treatment

**Major Depressive Disorder** — It is generally agreed that acute episodes of major depression require several months or longer of sustained pharmacologic therapy. Cymbalta should be administered at a total dose of 60 mg once daily. Patients should be periodically reassessed to determine the need for maintenance treatment and the appropriate dose for such treatment [see *Clinical Studies (14.1)*].

**Generalized Anxiety Disorder** — Generalized anxiety disorder is recognized as a chronic condition. The efficacy of Cymbalta in the treatment of GAD, that is, beyond 10 weeks, has not been systematically studied. The physician who elects to use Cymbalta for extended periods should periodically evaluate the long-term usefulness of the drug for the individual patient.

**Diabetic Peripheral Neuropathic Pain** — As the progression of diabetic peripheral neuropathy is highly variable and management of pain is empirical, the effectiveness of Cymbalta must be assessed individually. Efficacy beyond 12 weeks has not been systematically studied in placebo-controlled trials.

**Fibromyalgia** — Fibromyalgia is recognized as a chronic condition. The efficacy of Cymbalta in the management of fibromyalgia has been demonstrated in placebo-controlled studies up to 3 months. The efficacy of Cymbalta was not demonstrated in longer studies; however, continued treatment should be based on individual patient response.

## 2.3 Dosing in Special Populations

**Hepatic Insufficiency** — It is recommended that Cymbalta should ordinarily not be administered to patients with any hepatic insufficiency [see *Warnings and Precautions (5.12) and Use in Specific Populations (8.9)*].

**Severe Renal Impairment** — Cymbalta is not recommended for patients with end-stage renal disease or severe renal impairment (estimated creatinine clearance <30 mL/min) [see *Warnings and Precautions (5.12) and Use in Specific Populations (8.10)*].

**Elderly Patients** — No dose adjustment is recommended for elderly patients on the basis of age. As with any drug, caution should be exercised in treating the elderly. When individualizing the dosage in elderly patients, extra care should be taken when increasing the dose [see *Use in Specific Populations (8.5)*].

**Pregnant Women** — There are no adequate and well-controlled studies in pregnant women; therefore, Cymbalta should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus [see *Use in Specific Populations (8.1)*].

**Nursing Mothers** — Because the safety of duloxetine in infants is not known, nursing while on Cymbalta is not recommended [see *Use in Specific Populations (8.3)*].

## 2.4 Discontinuing Cymbalta

Symptoms associated with discontinuation of Cymbalta and other SSRIs and SNRIs have been reported. A gradual reduction in the dose rather than abrupt cessation is recommended whenever possible [see *Warnings and Precautions (5.6)*].

## 2.5 Switching Patients to or from a Monoamine Oxidase Inhibitor

106 At least 14 days should elapse between discontinuation of an MAOI and initiation of therapy with  
 107 Cymbalta. In addition, at least 5 days should be allowed after stopping Cymbalta before starting an MAOI  
 108 [see *Contraindications (4.1) and Warnings and Precautions (5.4)*].

### 109 **3 DOSAGE FORMS AND STRENGTHS**

110 Cymbalta is available as delayed release capsules:  
 111 20mg opaque green capsules imprinted with “Lilly 3235 20mg”  
 112 30mg opaque white and blue capsules imprinted with “Lilly 3240 30mg”  
 113 60mg opaque green and blue capsules imprinted with “Lilly 3237 60mg”

### 114 **4 CONTRAINDICATIONS**

#### 115 **4.1 Monoamine Oxidase Inhibitors**

116 Concomitant use in patients taking monoamine oxidase inhibitors (MAOIs) is contraindicated due  
 117 to the risk of serious, sometimes fatal, drug interactions with serotonergic drugs. These interactions may  
 118 include hyperthermia, rigidity, myoclonus, autonomic instability with possible rapid fluctuations of vital  
 119 signs, and mental status changes that include extreme agitation progressing to delirium and coma. These  
 120 reactions have also been reported in patients who have recently discontinued serotonin reuptake inhibitors  
 121 and are then started on an MAOI. Some cases presented with features resembling neuroleptic malignant  
 122 syndrome [see *Dosage and Administration (2.5) and Warnings and Precautions (5.4)*].

#### 123 **4.2 Uncontrolled Narrow-Angle Glaucoma**

124 In clinical trials, Cymbalta use was associated with an increased risk of mydriasis; therefore, its use  
 125 should be avoided in patients with uncontrolled narrow-angle glaucoma [see *Warnings and Precautions*  
 126 *(5.12)*].

### 127 **5 WARNINGS AND PRECAUTIONS**

#### 128 **5.1 Clinical Worsening and Suicide Risk**

129 Patients with major depressive disorder (MDD), both adult and pediatric, may experience  
 130 worsening of their depression and/or the emergence of suicidal ideation and behavior (suicidality) or  
 131 unusual changes in behavior, whether or not they are taking antidepressant medications, and this risk may  
 132 persist until significant remission occurs. Suicide is a known risk of depression and certain other  
 133 psychiatric disorders, and these disorders themselves are the strongest predictors of suicide. There has been  
 134 a long-standing concern, however, that antidepressants may have a role in inducing worsening of  
 135 depression and the emergence of suicidality in certain patients during the early phases of treatment.

136 Pooled analyses of short-term placebo-controlled trials of antidepressant drugs (SSRIs and others)  
 137 showed that these drugs increase the risk of suicidal thinking and behavior (suicidality) in children,  
 138 adolescents, and young adults (ages 18-24) with major depressive disorder (MDD) and other psychiatric  
 139 disorders. Short-term studies did not show an increase in the risk of suicidality with antidepressants  
 140 compared to placebo in adults beyond age 24; there was a reduction with antidepressants compared to  
 141 placebo in adults aged 65 and older.

142 The pooled analyses of placebo-controlled trials in children and adolescents with MDD, obsessive  
 143 compulsive disorder (OCD), or other psychiatric disorders included a total of 24 short-term trials of 9  
 144 antidepressant drugs in over 4400 patients. The pooled analyses of placebo-controlled trials in adults with  
 145 MDD or other psychiatric disorders included a total of 295 short-term trials (median duration of 2 months)  
 146 of 11 antidepressant drugs in over 77,000 patients. There was considerable variation in risk of suicidality  
 147 among drugs, but a tendency toward an increase in the younger patients for almost all drugs studied. There  
 148 were differences in absolute risk of suicidality across the different indications, with the highest incidence in  
 149 MDD. The risk of differences (drug vs placebo), however, were relatively stable within age strata and  
 150 across indications. These risk differences (drug-placebo difference in the number of cases of suicidality per  
 151 1000 patients treated) are provided in Table 1.  
 152  
 153

**Table 1**

Age Range	Drug-Placebo Difference in Number of Cases of Suicidality per 1000 Patients Treated
	Increases Compared to Placebo
<18	14 additional cases
18-24	5 additional cases

	Decreases Compared to Placebo
25-64	1 fewer case
≥65	6 fewer cases

No suicides occurred in any of the pediatric trials. There were suicides in the adult trials, but the number was not sufficient to reach any conclusion about drug effect on suicide.

It is unknown whether the suicidality risk extends to longer-term use, i.e., beyond several months. However, there is substantial evidence from placebo-controlled maintenance trials in adults with depression that the use of antidepressants can delay the recurrence of depression.

**All patients being treated with antidepressants for any indication should be monitored appropriately and observed closely for clinical worsening, suicidality, and unusual changes in behavior, especially during the initial few months of a course of drug therapy, or at times of dose changes, either increases or decreases.**

The following symptoms, anxiety, agitation, panic attacks, insomnia, irritability, hostility, aggressiveness, impulsivity, akathisia (psychomotor restlessness), hypomania, and mania, have been reported in adult and pediatric patients being treated with antidepressants for major depressive disorder as well as for other indications, both psychiatric and nonpsychiatric. Although a causal link between the emergence of such symptoms and either the worsening of depression and/or the emergence of suicidal impulses has not been established, there is concern that such symptoms may represent precursors to emerging suicidality.

Consideration should be given to changing the therapeutic regimen, including possibly discontinuing the medication, in patients whose depression is persistently worse, or who are experiencing emergent suicidality or symptoms that might be precursors to worsening depression or suicidality, especially if these symptoms are severe, abrupt in onset, or were not part of the patient's presenting symptoms.

If the decision has been made to discontinue treatment, medication should be tapered, as rapidly as is feasible, but with recognition that discontinuation can be associated with certain symptoms [*see Dosage and Administration (2.4) and Warnings and Precautions (5.6) for descriptions of the risks of discontinuation of Cymbalta*].

**Families and caregivers of patients being treated with antidepressants for major depressive disorder or other indications, both psychiatric and nonpsychiatric, should be alerted about the need to monitor patients for the emergence of agitation, irritability, unusual changes in behavior, and the other symptoms described above, as well as the emergence of suicidality, and to report such symptoms immediately to health care providers. Such monitoring should include daily observation by families and caregivers. Prescriptions for Cymbalta should be written for the smallest quantity of capsules consistent with good patient management, in order to reduce the risk of overdose.**

**Screening Patients for Bipolar Disorder** — A major depressive episode may be the initial presentation of bipolar disorder. It is generally believed (though not established in controlled trials) that treating such an episode with an antidepressant alone may increase the likelihood of precipitation of a mixed/manic episode in patients at risk for bipolar disorder. Whether any of the symptoms described above represent such a conversion is unknown. However, prior to initiating treatment with an antidepressant, patients with depressive symptoms should be adequately screened to determine if they are at risk for bipolar disorder; such screening should include a detailed psychiatric history, including a family history of suicide, bipolar disorder, and depression. It should be noted that Cymbalta (duloxetine) is not approved for use in treating bipolar depression.

## 5.2 Hepatotoxicity

There have been reports of hepatic failure, sometimes fatal, in patients treated with Cymbalta. These cases have presented as hepatitis with abdominal pain, hepatomegaly, and elevation of transaminase levels to more than twenty times the upper limit of normal with or without jaundice, reflecting a mixed or hepatocellular pattern of liver injury. Cymbalta should be discontinued in patients who develop jaundice or other evidence of clinically significant liver dysfunction and should not be resumed unless another cause can be established.

Cases of cholestatic jaundice with minimal elevation of transaminase levels have also been reported. Other postmarketing reports indicate that elevated transaminases, bilirubin, and alkaline phosphatase have occurred in patients with chronic liver disease or cirrhosis.

Cymbalta increased the risk of elevation of serum transaminase levels in development program clinical trials. Liver transaminase elevations resulted in the discontinuation of 0.3% (82/27,229) of Cymbalta-treated patients. In these patients, the median time to detection of the transaminase elevation was about two months. In placebo-controlled trials in any indication, elevation of ALT >3 times the upper limit of normal occurred in 1.1% (85/7,632) of Cymbalta-treated patients compared to 0.2% (13/5,578) of placebo-treated patients. In placebo-controlled studies using a fixed dose design, there was evidence of a dose response relationship for ALT and AST elevation of >3 times the upper limit of normal and >5 times the upper limit of normal, respectively.

Because it is possible that duloxetine and alcohol may interact to cause liver injury or that duloxetine may aggravate pre-existing liver disease, Cymbalta should ordinarily not be prescribed to patients with substantial alcohol use or evidence of chronic liver disease.

### 5.3 Orthostatic Hypotension and Syncope

Orthostatic hypotension and syncope have been reported with therapeutic doses of duloxetine. Syncope and orthostatic hypotension tend to occur within the first week of therapy but can occur at any time during duloxetine treatment, particularly after dose increases. The risk of blood pressure decreases may be greater in patients taking concomitant medications that induce orthostatic hypotension (such as antihypertensives) or are potent CYP1A2 inhibitors [see *Warnings and Precautions (5.10) and Drug Interactions (7.1)*] and in patients taking duloxetine at doses above 60 mg daily. Consideration should be given to discontinuing duloxetine in patients who experience symptomatic orthostatic hypotension and/or syncope during duloxetine therapy.

### 5.4 Serotonin Syndrome or Neuroleptic Malignant Syndrome (NMS)-like Reactions

The development of a potentially life-threatening serotonin syndrome or Neuroleptic Malignant Syndrome (NMS)-like reactions have been reported with SNRIs and SSRIs alone, including Cymbalta treatment, but particularly with concomitant use of serotonergic drugs (including triptans) with drugs which impair metabolism of serotonin (including MAOIs), or with antipsychotics or other dopamine antagonists. Serotonin syndrome symptoms may include mental status changes (e.g., agitation, hallucinations, coma), autonomic instability (e.g., tachycardia, labile blood pressure, hyperthermia), neuromuscular aberrations (e.g., hyperreflexia, incoordination) and/or gastrointestinal symptoms (e.g., nausea, vomiting, diarrhea). Serotonin syndrome, in its most severe form can resemble neuroleptic malignant syndrome, which includes hyperthermia, muscle rigidity, autonomic instability with possible rapid fluctuation of vital signs, and mental status changes. Patients should be monitored for the emergence of serotonin syndrome or NMS-like signs and symptoms.

The concomitant use of Cymbalta with MAOIs intended to treat depression is contraindicated [see *Contraindications (4.1)*].

If concomitant treatment of Cymbalta with a 5-hydroxytryptamine receptor agonist (triptan) is clinically warranted, careful observation of the patient is advised, particularly during treatment initiation and dose increases [see *Drug Interactions (7.15)*].

The concomitant use of Cymbalta with serotonin precursors (such as tryptophan) is not recommended [see *Drug Interactions (7.14)*].

Treatment with duloxetine and any concomitant serotonergic or antidopaminergic agents, including antipsychotics, should be discontinued immediately if the above events occur and supportive symptomatic treatment should be initiated.

### 5.5 Abnormal Bleeding

SSRIs and SNRIs, including duloxetine, may increase the risk of bleeding events. Concomitant use of aspirin, nonsteroidal anti-inflammatory drugs, warfarin, and other anti-coagulants may add to this risk. Case reports and epidemiological studies (case-control and cohort design) have demonstrated an association between use of drugs that interfere with serotonin reuptake and the occurrence of gastrointestinal bleeding. Bleeding events related to SSRIs and SNRIs use have ranged from ecchymoses, hematomas, epistaxis, and petechiae to life-threatening hemorrhages.

Patients should be cautioned about the risk of bleeding associated with the concomitant use of duloxetine and NSAIDs, aspirin, or other drugs that affect coagulation.

### 5.6 Discontinuation of Treatment with Cymbalta

Discontinuation symptoms have been systematically evaluated in patients taking duloxetine. Following abrupt or tapered discontinuation in placebo-controlled clinical trials, the following symptoms

260 occurred at a rate greater than or equal to 1% and at a significantly higher rate in duloxetine-treated patients  
 261 compared to those discontinuing from placebo: dizziness, nausea, headache, fatigue, paresthesia, vomiting,  
 262 irritability, nightmares, insomnia, diarrhea, anxiety, hyperhidrosis and vertigo.

263 During marketing of other SSRIs and SNRIs (serotonin and norepinephrine reuptake inhibitors),  
 264 there have been spontaneous reports of adverse events occurring upon discontinuation of these drugs,  
 265 particularly when abrupt, including the following: dysphoric mood, irritability, agitation, dizziness, sensory  
 266 disturbances (e.g., paresthesias such as electric shock sensations), anxiety, confusion, headache, lethargy,  
 267 emotional lability, insomnia, hypomania, tinnitus, and seizures. Although these events are generally  
 268 self-limiting, some have been reported to be severe.

269 Patients should be monitored for these symptoms when discontinuing treatment with Cymbalta. A  
 270 gradual reduction in the dose rather than abrupt cessation is recommended whenever possible. If intolerable  
 271 symptoms occur following a decrease in the dose or upon discontinuation of treatment, then resuming the  
 272 previously prescribed dose may be considered. Subsequently, the physician may continue decreasing the  
 273 dose but at a more gradual rate [*see Dosage and Administration (2.4)*].

### 274 **5.7 Activation of Mania/Hypomania**

275 In placebo-controlled trials in patients with major depressive disorder, activation of mania or  
 276 hypomania was reported in 0.1% (2/2,489) of duloxetine-treated patients and 0.1% (1/1,625) of  
 277 placebo-treated patients. No activation of mania or hypomania was reported in DPNP, GAD, or  
 278 fibromyalgia placebo-controlled trials. Activation of mania or hypomania has been reported in a small  
 279 proportion of patients with mood disorders who were treated with other marketed drugs effective in the  
 280 treatment of major depressive disorder. As with these other agents, Cymbalta should be used cautiously in  
 281 patients with a history of mania.

### 282 **5.8 Seizures**

283 Duloxetine has not been systematically evaluated in patients with a seizure disorder, and such  
 284 patients were excluded from clinical studies. In placebo-controlled clinical trials, seizures/convulsions  
 285 occurred in 0.03% (3/9,445) of patients treated with duloxetine and 0.01% (1/6,770) of patients treated with  
 286 placebo. Cymbalta should be prescribed with care in patients with a history of a seizure disorder.

### 287 **5.9 Effect on Blood Pressure**

288 In clinical trials across indications, relative to placebo, duloxetine treatment was associated with  
 289 mean increases of up to 2.1 mm Hg in systolic blood pressure and up to 2.3 mm Hg in diastolic blood  
 290 pressure. There was no significant difference in the frequency of sustained (3 consecutive visits) elevated  
 291 blood pressure. In a clinical pharmacology study designed to evaluate the effects of duloxetine on various  
 292 parameters, including blood pressure at supratherapeutic doses with an accelerated dose titration, there was  
 293 evidence of increases in supine blood pressure at doses up to 200 mg twice daily. At the highest 200 mg  
 294 twice daily dose, the increase in mean pulse rate was 5.0 to 6.8 beats and increases in mean blood pressure  
 295 were 4.7 to 6.8 mm Hg (systolic) and 4.5 to 7 mm Hg (diastolic) up to 12 hours after dosing.

296 Blood pressure should be measured prior to initiating treatment and periodically measured  
 297 throughout treatment [*see Adverse Reactions (6.7)*].

### 298 **5.10 Clinically Important Drug Interactions**

299 Both CYP1A2 and CYP2D6 are responsible for duloxetine metabolism.

#### 300 Potential for Other Drugs to Affect Cymbalta

301 CYP1A2 Inhibitors — Co-administration of Cymbalta with potent CYP1A2 inhibitors should be  
 302 avoided [*see Drug Interactions (7.1)*].

303 CYP2D6 Inhibitors — Because CYP2D6 is involved in duloxetine metabolism, concomitant use of  
 304 duloxetine with potent inhibitors of CYP2D6 would be expected to, and does, result in higher  
 305 concentrations (on average of 60%) of duloxetine [*see Drug Interactions (7.2)*].

#### 306 Potential for Cymbalta to Affect Other Drugs

307 Drugs Metabolized by CYP2D6 — Co-administration of Cymbalta with drugs that are extensively  
 308 metabolized by CYP2D6 and that have a narrow therapeutic index, including certain antidepressants  
 309 (tricyclic antidepressants [TCAs], such as nortriptyline, amitriptyline, and imipramine), phenothiazines and  
 310 Type 1C antiarrhythmics (e.g., propafenone, flecainide), should be approached with caution. Plasma TCA  
 311 concentrations may need to be monitored and the dose of the TCA may need to be reduced if a TCA is  
 312 co-administered with Cymbalta. Because of the risk of serious ventricular arrhythmias and sudden death  
 313 potentially associated with elevated plasma levels of thioridazine, Cymbalta and thioridazine should not be  
 314 co-administered [*see Drug Interactions (7.9)*].

315 Other Clinically Important Drug Interactions

316 Alcohol — Use of Cymbalta concomitantly with heavy alcohol intake may be associated with  
317 severe liver injury. For this reason, Cymbalta should ordinarily not be prescribed for patients with  
318 substantial alcohol use [*see Warnings and Precautions (5.2) and Drug Interactions (7.16)*].

319 CNS Acting Drugs — Given the primary CNS effects of Cymbalta, it should be used with caution  
320 when it is taken in combination with or substituted for other centrally acting drugs, including those with a  
321 similar mechanism of action [*see Warnings and Precautions (5.10) and Drug Interactions (7.17)*].

322 **5.11 Hyponatremia**

323 Hyponatremia may occur as a result of treatment with SSRIs and SNRIs, including Cymbalta. In  
324 many cases, this hyponatremia appears to be the result of the syndrome of inappropriate antidiuretic  
325 hormone secretion (SIADH). Cases with serum sodium lower than 110 mmol/L have been reported and  
326 appeared to be reversible when Cymbalta was discontinued. Elderly patients may be at greater risk of  
327 developing hyponatremia with SSRIs and SNRIs. Also, patients taking diuretics or who are otherwise  
328 volume depleted may be at greater risk [*see Use in Specific Populations (8.5)*]. Discontinuation of  
329 Cymbalta should be considered in patients with symptomatic hyponatremia and appropriate medical  
330 intervention should be instituted.

331 Signs and symptoms of hyponatremia include headache, difficulty concentrating, memory  
332 impairment, confusion, weakness, and unsteadiness, which may lead to falls. More severe and/or acute  
333 cases have been associated with hallucination, syncope, seizure, coma, respiratory arrest, and death.

334 **5.12 Use in Patients with Concomitant Illness**

335 Clinical experience with Cymbalta in patients with concomitant systemic illnesses is limited. There  
336 is no information on the effect that alterations in gastric motility may have on the stability of Cymbalta's  
337 enteric coating. In extremely acidic conditions, Cymbalta, unprotected by the enteric coating, may undergo  
338 hydrolysis to form naphthol. Caution is advised in using Cymbalta in patients with conditions that may  
339 slow gastric emptying (e.g., some diabetics).

340 Cymbalta has not been systematically evaluated in patients with a recent history of myocardial  
341 infarction or unstable coronary artery disease. Patients with these diagnoses were generally excluded from  
342 clinical studies during the product's premarketing testing.

343 Hepatic Insufficiency — Cymbalta should ordinarily not be used in patients with hepatic  
344 insufficiency [*see Dosage and Administration (2.3), Warnings and Precautions (5.2), and Use in Specific  
345 Populations (8.9)*].

346 Severe Renal Impairment — Cymbalta should ordinarily not be used in patients with end-stage  
347 renal disease or severe renal impairment (creatinine clearance <30 mL/min). Increased plasma  
348 concentration of duloxetine, and especially of its metabolites, occur in patients with end-stage renal disease  
349 (requiring dialysis) [*see Dosage and Administration (2.3) and Use in Specific Populations (8.10)*].

350 Controlled Narrow-Angle Glaucoma — In clinical trials, Cymbalta was associated with an  
351 increased risk of mydriasis; therefore, it should be used cautiously in patients with controlled narrow-angle  
352 glaucoma [*see Contraindications (4.2)*].

353 Glycemic Control in Patients with Diabetes — As observed in DPNP trials, Cymbalta treatment  
354 worsens glycemic control in some patients with diabetes. In three clinical trials of Cymbalta for the  
355 management of neuropathic pain associated with diabetic peripheral neuropathy, the mean duration of  
356 diabetes was approximately 12 years, the mean baseline fasting blood glucose was 176 mg/dL, and the  
357 mean baseline hemoglobin A<sub>1c</sub> (HbA<sub>1c</sub>) was 7.8%. In the 12-week acute treatment phase of these studies,  
358 Cymbalta was associated with a small increase in mean fasting blood glucose as compared to placebo. In  
359 the extension phase of these studies, which lasted up to 52 weeks, mean fasting blood glucose increased by  
360 12 mg/dL in the Cymbalta group and decreased by 11.5 mg/dL in the routine care group. HbA<sub>1c</sub> increased  
361 by 0.5% in the Cymbalta and by 0.2% in the routine care groups.

362 **5.13 Urinary Hesitation and Retention**

363 Cymbalta is in a class of drugs known to affect urethral resistance. If symptoms of urinary  
364 hesitation develop during treatment with Cymbalta, consideration should be given to the possibility that  
365 they might be drug-related.

366 In post marketing experience, cases of urinary retention have been observed. In some instances of  
367 urinary retention associated with duloxetine use, hospitalization and/or catheterization has been needed.

368 **5.14 Laboratory Tests**

369 No specific laboratory tests are recommended.

## 370 6 ADVERSE REACTIONS

### 371 6.1 Clinical Trial Data Sources

372 The data described below reflect exposure to duloxetine in placebo-controlled trials for MDD  
373 (N=2,327), GAD (N=668), DPNP (N=568), and FM (N=876). The population studied was 17 to 89 years of  
374 age; 64.8%, 64.7%, 38.7%, and 94.6% female; and 85.5%, 84.6%, 77.6%, and 88% Caucasian for MDD,  
375 GAD, DPNP, and FM, respectively. Most patients received doses of a total of 60 to 120 mg per day [*see*  
376 *Clinical Studies (14)*].

377 The stated frequencies of adverse reactions represent the proportion of individuals who  
378 experienced, at least once, a treatment-emergent adverse reaction of the type listed. A reaction was  
379 considered treatment-emergent if it occurred for the first time or worsened while receiving therapy  
380 following baseline evaluation. Reactions reported during the studies were not necessarily caused by the  
381 therapy, and the frequencies do not reflect investigator impression (assessment) of causality.

382 Because clinical trials are conducted under widely varying conditions, adverse reaction rates  
383 observed in the clinical trials of a drug cannot be directly compared to rates in the clinical trials of another  
384 drug and may not reflect the rates observed in practice.

### 385 6.2 Adverse Reactions Reported as Reasons for Discontinuation of Treatment in Placebo- 386 Controlled Trials

387 Major Depressive Disorder — Approximately 9% (209/2,327) of the patients who received  
388 duloxetine in placebo-controlled trials for MDD discontinued treatment due to an adverse reaction,  
389 compared with 4.7% (68/1,460) of the patients receiving placebo. Nausea (duloxetine 1.3%, placebo 0.5%)  
390 was the only common adverse reaction reported as a reason for discontinuation and considered to be drug-  
391 related (i.e., discontinuation occurring in at least 1% of the duloxetine-treated patients and at a rate of at  
392 least twice that of placebo).

393 Generalized Anxiety Disorder — Approximately 15.3% (102/668) of the patients who received  
394 duloxetine in placebo-controlled trials for GAD discontinued treatment due to an adverse reaction,  
395 compared with 4.0% (20/495) for placebo. Common adverse reactions reported as a reason for  
396 discontinuation and considered to be drug-related (as defined above) included nausea (duloxetine 3.7%,  
397 placebo 0.2%), vomiting (duloxetine 1.3%, placebo 0.0%), and dizziness (duloxetine 1.0%, placebo 0.2%).

398 Diabetic Peripheral Neuropathic Pain — Approximately 14.3% (81/568) of the patients who  
399 received duloxetine in placebo-controlled trials for DPNP discontinued treatment due to an adverse  
400 reaction, compared with 7.2% (16/223) for placebo. Common adverse reactions reported as a reason for  
401 discontinuation and considered to be drug-related (as defined above) were nausea (duloxetine 3.5%,  
402 placebo 0.4%), dizziness (duloxetine 1.6%, placebo 0.4%), somnolence (duloxetine 1.6%, placebo 0.0%),  
403 and fatigue (duloxetine 1.1%, placebo 0.0%).

404 Fibromyalgia — Approximately 19.5% (171/876) of the patients who received duloxetine in 3 to 6  
405 month placebo-controlled trials for FM discontinued treatment due to an adverse reaction, compared with  
406 11.8% (63/535) for placebo. Common adverse reactions reported as a reason for discontinuation and  
407 considered to be drug-related (as defined above) included nausea (duloxetine 1.9%, placebo 0.7%),  
408 somnolence (duloxetine 1.5%, placebo 0.0%), and fatigue (duloxetine 1.3%, placebo 0.2%).

### 409 6.3 Adverse Reactions Occurring at an Incidence of 5% or More and at least Twice Placebo 410 Among Duloxetine-Treated Patients in Placebo-Controlled Trials

411 Pooled Trials for all Approved Indications — The most commonly observed adverse reactions in  
412 Cymbalta-treated patients (incidence of at least 5% and at least twice the incidence in placebo patients)  
413 were nausea, dry mouth, constipation, somnolence, hyperhidrosis, and decreased appetite.

414 In addition to the adverse reactions listed above, DPNP trials also included dizziness and asthenia.

### 415 6.4 Adverse Reactions Occurring at an Incidence of 5% or More Among Duloxetine-Treated 416 Patients in Placebo-Controlled Trials

417 Table 2 gives the incidence of treatment-emergent adverse reactions in placebo-controlled trials for  
418 approved indications that occurred in 5% or more of patients treated with duloxetine and with an incidence  
419 greater than placebo.

420  
421 **Table 2: Treatment-Emergent Adverse Reactions: Incidence of 5% or More in Placebo-Controlled  
422 Trials of Approved Indications**

	Percentage of Patients Reporting Reaction
--	---

<b>Adverse Reaction</b>	<b>Cymbalta (N=4843)</b>	<b>Placebo (N=3048)</b>
Nausea	25	9

## 6.6 Effects on Male and Female Sexual Function

Changes in sexual desire, sexual performance and sexual satisfaction often occur as manifestations of psychiatric disorders or diabetes, but they may also be a consequence of pharmacologic treatment. Because adverse sexual reactions are presumed to be voluntarily underreported, the Arizona Sexual

477  
478  
479  
480

481 Experience Scale (ASEX), a validated measure designed to identify sexual side effects, was used  
 482 prospectively in 4 MDD placebo-controlled trials. In these trials, as shown in Table 6 below, patients  
 483 treated with Cymbalta experienced significantly more sexual dysfunction, as measured by the total score on  
 484 the ASEX, than did patients treated with placebo. Gender analysis showed that this difference occurred  
 485 only in males. Males treated with Cymbalta experienced more difficulty with ability to reach orgasm  
 486 (ASEX Item 4) than males treated with placebo. Females did not experience more sexual dysfunction on  
 487 Cymbalta than on placebo as measured by ASEX total score. Negative numbers signify an improvement  
 488 from a baseline level of dysfunction, which is commonly seen in depressed patients. Physicians should  
 489 routinely inquire about possible sexual side effects.

491 **Table 6: Mean Change in ASEX Scores by Gender**  
 492 **in MDD Placebo-Controlled Trials**  
 493

	Male Patients <sup>a</sup>		Female Patients <sup>a</sup>	
	Cymbalta (n=175)	Placebo (n=83)	Cymbalta (n=241)	Placebo (n=126)

496 <sup>c</sup> p<0.001 versus placebo  
 497

### 498 **6.7 Vital Sign Changes**

499 In clinical trials across indications, relative to placebo, duloxetine treatment was associated with  
 500 mean increases of up to 2.1 mm Hg in systolic blood pressure and up to 2.3 mm Hg in diastolic blood  
 501 pressure. There was no significant difference in the frequency of sustained (3 consecutive visits) elevated  
 502 blood pressure [see *Warnings and Precautions (5.3 and 5.9)*].

503 Duloxetine treatment, for up to 26 weeks in placebo-controlled trials typically caused a small  
 504 increase in heart rate compared to placebo of up to 3-4 beats per minute.

### 505 **6.8 Weight Changes**

506 In placebo-controlled clinical trials, MDD and GAD patients treated with Cymbalta for up to 10  
 507 weeks experienced a mean weight loss of approximately 0.5 kg, compared with a mean weight gain of  
 508 approximately 0.2 kg in placebo-treated patients. In DPN placebo-controlled clinical trials, patients treated  
 509 with Cymbalta for up to 13-weeks experienced a mean weight loss of approximately 1.1 kg, compared with  
 510 a mean weight gain of approximately 0.2 kg in placebo-treated patients. In fibromyalgia studies, patients  
 511 treated with Cymbalta for up to 26 weeks experienced a mean weight loss of approximately 0.4 kg  
 512 compared with a mean weight gain of approximately 0.3 kg in placebo-treated patients. In one long-term  
 513 fibromyalgia 60-week uncontrolled study, duloxetine patients had a mean weight increase of 0.7 kg.

### 514 **6.9 Laboratory Changes**

515 Cymbalta treatment in placebo-controlled clinical trials, was associated with small mean increases  
 516 from baseline to endpoint in ALT, AST, CPK, and alkaline phosphatase; infrequent, modest, transient,  
 517 abnormal values were observed for these analytes in Cymbalta-treated patients when compared with  
 518 placebo-treated patients [see *Warnings and Precautions (5.2)*].

### 519 **6.10 Electrocardiogram Changes**

520 Electrocardiograms were obtained from duloxetine-treated patients and placebo-treated patients in  
 521 clinical trials lasting up to 13 weeks. No clinically significant differences were observed for QTc, QT, PR,  
 522 and QRS intervals between duloxetine-treated and placebo-treated patients. There were no differences in  
 523 clinically meaningful QTcF elevations between duloxetine and placebo. In a positive-controlled study in  
 524 healthy volunteers using duloxetine up to 200 mg twice daily, no prolongation of the corrected QT interval  
 525 was observed.

## 526 6.11 Other Adverse Reactions Observed During the Premarketing and Postmarketing Clinical 527 Trial Evaluation of Duloxetine

528 Following is a list of treatment-emergent adverse reactions reported by patients treated with  
529 duloxetine in clinical trials. In clinical trials of all indications, 27,229 patients were treated with duloxetine.  
530 Of these, 29% (7,886) took duloxetine for at least 6 months, and 13.3% (3,614) for at least one year. The  
531 following listing is not intended to include reactions (1) already listed in previous tables or elsewhere in  
532 labeling, (2) for which a drug cause was remote, (3) which were so general as to be uninformative,  
533 (4) which were not considered to have significant clinical implications, or (5) which occurred at a rate  
534 equal to or less than placebo.

535 Reactions are categorized by body system according to the following definitions: frequent adverse  
536 reactions are those occurring in at least 1/100 patients; infrequent adverse reactions are those occurring in  
537 1/100 to 1/1000 patients; rare reactions are those occurring in fewer than 1/1000 patients.

538 **Cardiac Disorders** — *Frequent*: palpitations; *Infrequent*: myocardial infarction and tachycardia.

539 **Ear and Labyrinth Disorders** — *Frequent*: vertigo; *Infrequent*: ear pain and tinnitus.

540 **Endocrine Disorders** — *Infrequent*: hypothyroidism.

541 **Eye Disorders** — *Frequent*: vision blurred; *Infrequent*: diplopia and visual disturbance.

542 **Gastrointestinal Disorders** — *Frequent*: flatulence; *Infrequent*: eructation, gastritis, halitosis, and  
543 stomatitis; *Rare*: gastric ulcer, hematochezia, and melena.

544 **General Disorders and Administration Site Conditions** — *Frequent*: chills/rigors;  
545 *Infrequent*: feeling abnormal, feeling hot and/or cold, malaise, and thirst; *Rare*: gait disturbance.

546 **Infections and Infestations** — *Infrequent*: gastroenteritis and laryngitis.

547 **Investigations** — *Frequent*: weight increased; *Infrequent*: blood cholesterol increased.

548 **Metabolism and Nutrition Disorders** — *Infrequent*: dehydration and hyperlipidemia;  
549 *Rare*: dyslipidemia.

550 **Musculoskeletal and Connective Tissue Disorders** — *Frequent*: musculoskeletal pain;  
551 *Infrequent*: muscle tightness and muscle twitching.

552 **Nervous System Disorders** — *Frequent*: dysgeusia, lethargy, and parasthesia/hypoesthesia;  
553 *Infrequent*: disturbance in attention, dyskinesia, myoclonus, and poor quality sleep; *Rare*: dysarthria.

554 **Psychiatric Disorders** — *Frequent*: abnormal dreams and sleep disorder; *Infrequent*: apathy,  
555 bruxism, disorientation/confusional state, irritability, mood swings, and suicide attempt; *Rare*: completed  
556 suicide.

557 **Renal and Urinary Disorders** — *Infrequent*: dysuria, micturition urgency, nocturia, polyuria, and  
558 urine odor abnormal.

559 **Reproductive System and Breast Disorders** — *Frequent*: anorgasmia/orgasm abnormal;  
560 *Infrequent*: menopausal symptoms, and sexual dysfunction.

561 **Respiratory, Thoracic and Mediastinal Disorders** — *Frequent*: yawning; *Infrequent*: throat  
562 tightness.

563 **Skin and Subcutaneous Tissue Disorders** — *Infrequent*: cold sweat, dermatitis contact, erythema,  
564 increased tendency to bruise, night sweats, and photosensitivity reaction; *Rare*: ecchymosis.

565 **Vascular Disorders** — *Frequent*: hot flush; *Infrequent*: flushing, orthostatic hypotension, and  
566 peripheral coldness.

## 567 6.12 Postmarketing Spontaneous Reports

568 The following adverse reactions have been identified during postapproval use of Cymbalta.  
569 Because these reactions are reported voluntarily from a population of uncertain size, it is not always  
570 possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

571 Adverse reactions reported since market introduction that were temporally related to duloxetine  
572 therapy and not mentioned elsewhere in labeling include: anaphylactic reaction, aggression and anger  
573 (particularly early in treatment or after treatment discontinuation), angioneurotic edema, erythema  
574 multiforme, extrapyramidal disorder, glaucoma, gynecological bleeding, hallucinations, hyperglycemia,  
575 hypersensitivity, hypertensive crisis, muscle spasm, rash, restless legs syndrome, seizures upon treatment  
576 discontinuation, supraventricular arrhythmia, tinnitus (upon treatment discontinuation), trismus, and  
577 urticaria.

578 Serious skin reactions including Stevens-Johnson Syndrome that have required drug  
579 discontinuation and/or hospitalization have been reported with duloxetine.

## 580 7 DRUG INTERACTIONS

581 Both CYP1A2 and CYP2D6 are responsible for duloxetine metabolism.

#### 582 **7.1 Inhibitors of CYP1A2**

583 When duloxetine 60 mg was co-administered with fluvoxamine 100 mg, a potent CYP1A2  
584 inhibitor, to male subjects (n=14) duloxetine AUC was increased approximately 6-fold, the C<sub>max</sub> was  
585 increased about 2.5-fold, and duloxetine t<sub>1/2</sub> was increased approximately 3-fold. Other drugs that inhibit  
586 CYP1A2 metabolism include cimetidine and quinolone antimicrobials such as ciprofloxacin and enoxacin  
587 [see *Warnings and Precautions (5.10)*].

#### 588 **7.2 Inhibitors of CYP2D6**

589 Concomitant use of duloxetine (40 mg once daily) with paroxetine (20 mg once daily) increased  
590 the concentration of duloxetine AUC by about 60%, and greater degrees of inhibition are expected with  
591 higher doses of paroxetine. Similar effects would be expected with other potent CYP2D6 inhibitors  
592 (e.g., fluoxetine, quinidine) [see *Warnings and Precautions (5.10)*].

#### 593 **7.3 Dual Inhibition of CYP1A2 and CYP2D6**

594 Concomitant administration of duloxetine 40 mg twice daily with fluvoxamine 100 mg, a potent  
595 CYP1A2 inhibitor, to CYP2D6 poor metabolizer subjects (n=14) resulted in a 6-fold increase in duloxetine  
596 AUC and C<sub>max</sub>.

#### 597 **7.4 Drugs that Interfere with Hemostasis (e.g., NSAIDs, Aspirin, and Warfarin)**

598 Serotonin release by platelets plays an important role in hemostasis. Epidemiological studies of the  
599 case-control and cohort design that have demonstrated an association between use of psychotropic drugs  
600 that interfere with serotonin reuptake and the occurrence of upper gastrointestinal bleeding have also shown  
601 that concurrent use of an NSAID or aspirin may potentiate this risk of bleeding. Altered anticoagulant  
602 effects, including increased bleeding, have been reported when SSRIs or SNRIs are coadministered with  
603 warfarin. Patients receiving warfarin therapy should be carefully monitored when duloxetine is initiated or  
604 discontinued [see *Warnings and Precautions (5.5)*].

#### 605 **7.5 Lorazepam**

606 Under steady-state conditions for duloxetine (60 mg Q 12 hours) and lorazepam (2 mg Q 12 hours),  
607 the pharmacokinetics of duloxetine were not affected by co-administration.

#### 608 **7.6 Temazepam**

609 Under steady-state conditions for duloxetine (20 mg qhs) and temazepam (30 mg qhs), the  
610 pharmacokinetics of duloxetine were not affected by co-administration.

#### 611 **7.7 Drugs that Affect Gastric Acidity**

612 Cymbalta has an enteric coating that resists dissolution until reaching a segment of the  
613 gastrointestinal tract where the pH exceeds 5.5. In extremely acidic conditions, Cymbalta, unprotected by  
614 the enteric coating, may undergo hydrolysis to form naphthol. Caution is advised in using Cymbalta in  
615 patients with conditions that may slow gastric emptying (e.g., some diabetics). Drugs that raise the  
616 gastrointestinal pH may lead to an earlier release of duloxetine. However, co-administration of Cymbalta  
617 with aluminum- and magnesium-containing antacids (51 mEq) or Cymbalta with famotidine, had no  
618 significant effect on the rate or extent of duloxetine absorption after administration of a 40 mg oral dose. It  
619 is unknown whether the concomitant administration of proton pump inhibitors affects duloxetine  
620 absorption [see *Warnings and Precautions (5.12)*].

#### 621 **7.8 Drugs Metabolized by CYP1A2**

622 *In vitro* drug interaction studies demonstrate that duloxetine does not induce CYP1A2 activity.  
623 Therefore, an increase in the metabolism of CYP1A2 substrates (e.g., theophylline, caffeine) resulting from  
624 induction is not anticipated, although clinical studies of induction have not been performed. Duloxetine is  
625 an inhibitor of the CYP1A2 isoform in *in vitro* studies, and in two clinical studies the average (90%  
626 confidence interval) increase in theophylline AUC was 7% (1%-15%) and 20% (13%-27%) when  
627 co-administered with duloxetine (60 mg twice daily).

#### 628 **7.9 Drugs Metabolized by CYP2D6**

629 Duloxetine is a moderate inhibitor of CYP2D6. When duloxetine was administered (at a dose of  
630 60 mg twice daily) in conjunction with a single 50 mg dose of desipramine, a CYP2D6 substrate, the AUC  
631 of desipramine increased 3-fold [see *Warnings and Precautions (5.10)*].

#### 632 **7.10 Drugs Metabolized by CYP2C9**

633 Duloxetine does not inhibit the *in vitro* enzyme activity of CYP2C9. Inhibition of the metabolism  
634 of CYP2C9 substrates is therefore not anticipated, although clinical studies have not been performed.

#### 635 **7.11 Drugs Metabolized by CYP3A**

636 Results of *in vitro* studies demonstrate that duloxetine does not inhibit or induce CYP3A activity.  
637 Therefore, an increase or decrease in the metabolism of CYP3A substrates (e.g., oral contraceptives and  
638 other steroidal agents) resulting from induction or inhibition is not anticipated, although clinical studies  
639 have not been performed.

#### 640 **7.12 Drugs Metabolized by CYP2C19**

641 Results of *in vitro* studies demonstrate that duloxetine does not inhibit CYP2C19 activity at  
642 therapeutic concentrations. Inhibition of the metabolism of CYP2C19 substrates is therefore not  
643 anticipated, although clinical studies have not been performed.

#### 644 **7.13 Monoamine Oxidase Inhibitors**

645 *[see Dosage and Administration (2.5), Contraindications (4.1), and Warnings and Precautions*  
646 *(5.4)].*

#### 647 **7.14 Serotonergic Drugs**

648 Based on the mechanism of action of SNRIs and SSRIs, including Cymbalta, and the potential for  
649 serotonin syndrome, caution is advised when Cymbalta is co-administered with other drugs that may affect  
650 the serotonergic neurotransmitter systems, such as triptans, linezolid (an antibiotic which is a reversible  
651 non-selective MAOI), lithium, tramadol, or St. John's Wort. The concomitant use of Cymbalta with other  
652 SSRIs, SNRIs or tryptophan is not recommended *[see Warnings and Precautions (5.4)].*

#### 653 **7.15 Triptans**

654 There have been rare postmarketing reports of serotonin syndrome with use of an SSRI and a  
655 triptan. If concomitant treatment of Cymbalta with a triptan is clinically warranted, careful observation of  
656 the patient is advised, particularly during treatment initiation and dose increases *[see Warnings and*  
657 *Precautions (5.4)].*

#### 658 **7.16 Alcohol**

659 When Cymbalta and ethanol were administered several hours apart so that peak concentrations of  
660 each would coincide, Cymbalta did not increase the impairment of mental and motor skills caused by  
661 alcohol.

662 In the Cymbalta clinical trials database, three Cymbalta-treated patients had liver injury as  
663 manifested by ALT and total bilirubin elevations, with evidence of obstruction. Substantial intercurrent  
664 ethanol use was present in each of these cases, and this may have contributed to the abnormalities seen *[see*  
665 *Warnings and Precautions (5.2 and 5.10)].*

#### 666 **7.17 CNS Drugs**

667 *[see Warnings and Precautions (5.10)].*

#### 668 **7.18 Drugs Highly Bound to Plasma Protein**

669 Because duloxetine is highly bound to plasma protein, administration of Cymbalta to a patient  
670 taking another drug that is highly protein bound may cause increased free concentrations of the other drug,  
671 potentially resulting in adverse reactions.

### 672 **8 USE IN SPECIFIC POPULATIONS**

#### 673 **8.1 Pregnancy**

674 Teratogenic Effects, Pregnancy Category C — In animal reproduction studies, duloxetine has been  
675 shown to have adverse effects on embryo/fetal and postnatal development.

676 When duloxetine was administered orally to pregnant rats and rabbits during the period of  
677 organogenesis, there was no evidence of teratogenicity at doses up to 45 mg/kg/day (7 times the maximum  
678 recommended human dose [MRHD, 60 mg/day] and 4 times the human dose of 120 mg/day on a mg/m<sup>2</sup>  
679 basis, in rat; 15 times the MRHD and 7 times the human dose of 120 mg/day on a mg/m<sup>2</sup> basis in rabbit).  
680 However, fetal weights were decreased at this dose, with a no-effect dose of 10 mg/kg/day (2 times the  
681 MRHD and ≈1 times the human dose of 120 mg/day on a mg/m<sup>2</sup> basis in rat; 3 times the MRHD and  
682 2 times the human dose of 120 mg/day on a mg/m<sup>2</sup> basis in rabbits).

683 When duloxetine was administered orally to pregnant rats throughout gestation and lactation, the  
684 survival of pups to 1 day postpartum and pup body weights at birth and during the lactation period were  
685 decreased at a dose of 30 mg/kg/day (5 times the MRHD and 2 times the human dose of 120 mg/day on a

686 mg/m<sup>2</sup> basis); the no-effect dose was 10 mg/kg/day. Furthermore, behaviors consistent with increased  
687 reactivity, such as increased startle response to noise and decreased habituation of locomotor activity, were  
688 observed in pups following maternal exposure to 30 mg/kg/day. Post-weaning growth and reproductive  
689 performance of the progeny were not affected adversely by maternal duloxetine treatment.

690 There are no adequate and well-controlled studies in pregnant women; therefore, duloxetine should  
691 be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

692 Nonteratogenic Effects — Neonates exposed to SSRIs or serotonin and norepinephrine reuptake  
693 inhibitors (SNRIs), late in the third trimester have developed complications requiring prolonged  
694 hospitalization, respiratory support, and tube feeding. Such complications can arise immediately upon  
695 delivery. Reported clinical findings have included respiratory distress, cyanosis, apnea, seizures,  
696 temperature instability, feeding difficulty, vomiting, hypoglycemia, hypotonia, hypertonia, hyperreflexia,  
697 tremor, jitteriness, irritability, and constant crying. These features are consistent with either a direct toxic  
698 effect of SSRIs and SNRIs or, possibly, a drug discontinuation syndrome. It should be noted that, in some  
699 cases, the clinical picture is consistent with serotonin syndrome [see *Warnings and Precautions* (5.4)].

700 When treating pregnant women with Cymbalta during the third trimester, the physician should  
701 carefully consider the potential risks and benefits of treatment. The physician may consider tapering  
702 Cymbalta in the third trimester [see *Dosage and Administration* (2.3)].

## 703 **8.2 Labor and Delivery**

704 The effect of duloxetine on labor and delivery in humans is unknown. Duloxetine should be used  
705 during labor and delivery only if the potential benefit justifies the potential risk to the fetus.

## 706 **8.3 Nursing Mothers**

707 Duloxetine is excreted into the milk of lactating women. The estimated daily infant dose on a  
708 mg/kg basis is approximately 0.14% of the maternal dose. Because the safety of duloxetine in infants is not  
709 known, nursing while on Cymbalta is not recommended. However, if the physician determines that the  
710 benefit of duloxetine therapy for the mother outweighs any potential risk to the infant, no dosage  
711 adjustment is required as lactation did not influence duloxetine pharmacokinetics.

712 The disposition of duloxetine was studied in 6 lactating women who were at least 12 weeks  
713 postpartum. Duloxetine 40 mg twice daily was given for 3.5 days. Like many other drugs, duloxetine is  
714 detected in breast milk, and steady state concentrations in breast milk are about one-fourth those in plasma.  
715 The amount of duloxetine in breast milk is approximately 7 µg/day while on 40 mg BID dosing. The  
716 excretion of duloxetine metabolites into breast milk was not examined. Because the safety of duloxetine in  
717 infants is not known, nursing while on Cymbalta is not recommended [see *Dosing and Administration*  
718 (2.3)].

## 719 **8.4 Pediatric Use**

720 Safety and effectiveness in the pediatric population have not been established [see *Boxed Warning*  
721 *and Warnings and Precautions* (5.1)]. Anyone considering the use of Cymbalta in a child or adolescent  
722 must balance the potential risks with the clinical need.

## 723 **8.5 Geriatric Use**

724 Of the 2,418 patients in premarketing clinical studies of Cymbalta for MDD, 5.9% (143) were  
725 65 years of age or over. Of the 1,074 patients in the DPNP premarketing studies, 33% (357) were 65 years  
726 of age or over. Of the 1,761 patients in FM premarketing studies, 7.9% (140) were 65 years of age or over.  
727 Premarketing clinical studies of GAD did not include sufficient numbers of subjects age 65 or over to  
728 determine whether they respond differently from younger subjects. In the MDD, DPNP, and FM studies, no  
729 overall differences in safety or effectiveness were observed between these subjects and younger subjects,  
730 and other reported clinical experience has not identified differences in responses between the elderly and  
731 younger patients, but greater sensitivity of some older individuals cannot be ruled out. SSRIs and SNRIs,  
732 including Cymbalta have been associated with cases of clinically significant hyponatremia in elderly  
733 patients, who may be at greater risk for this adverse event [see *Warnings and Precautions* (5.11)].

734 The pharmacokinetics of duloxetine after a single dose of 40 mg were compared in healthy elderly  
735 females (65 to 77 years) and healthy middle-age females (32 to 50 years). There was no difference in the  
736 C<sub>max</sub>, but the AUC of duloxetine was somewhat (about 25%) higher and the half-life about 4 hours longer  
737 in the elderly females. Population pharmacokinetic analyses suggest that the typical values for clearance  
738 decrease by approximately 1% for each year of age between 25 to 75 years of age; but age as a predictive  
739 factor only accounts for a small percentage of between-patient variability. Dosage adjustment based on the  
740 age of the patient is not necessary [see *Dosage and Administration* (2.3)].

**741 8.6 Gender**

742 Duloxetine's half-life is similar in men and women. Dosage adjustment based on gender is not  
743 necessary.

**744 8.7 Smoking Status**

745 Duloxetine bioavailability (AUC) appears to be reduced by about one-third in smokers. Dosage  
746 modifications are not recommended for smokers.

**747 8.8 Race**

748 No specific pharmacokinetic study was conducted to investigate the effects of race.

**749 8.9 Hepatic Insufficiency**

750 Patients with clinically evident hepatic insufficiency have decreased duloxetine metabolism and  
751 elimination. After a single 20 mg dose of Cymbalta, 6 cirrhotic patients with moderate liver  
752 impairment (Child-Pugh Class B) had a mean plasma duloxetine clearance about 15% that of age- and  
753 gender-matched healthy subjects, with a 5-fold increase in mean exposure (AUC). Although  $C_{max}$  was  
754 similar to normals in the cirrhotic patients, the half-life was about 3 times longer [*see Dosage and*  
755 *Administration (2.3) and Warnings and Precautions (5.12)*].

**756 8.10 Severe Renal Impairment**

757 Limited data are available on the effects of duloxetine in patients with end-stage renal  
758 disease (ESRD). After a single 60 mg dose of duloxetine,  $C_{max}$  and AUC values were approximately  
759 100% greater in patients with end-stage renal disease receiving chronic intermittent hemodialysis than in  
760 subjects with normal renal function. The elimination half-life, however, was similar in both groups. The  
761 AUCs of the major circulating metabolites, 4-hydroxy duloxetine glucuronide and 5-hydroxy, 6-methoxy  
762 duloxetine sulfate, largely excreted in urine, were approximately 7- to 9-fold higher and would be expected  
763 to increase further with multiple dosing. Population PK analyses suggest that mild to moderate degrees of  
764 renal dysfunction (estimated CrCl 30-80 mL/min) have no significant effect on duloxetine apparent  
765 clearance [*see Dosage and Administration (2.3) and Warnings and Precautions (5.12)*].

**766 9 DRUG ABUSE AND DEPENDENCE****767 9.2 Abuse**

768 In animal studies, duloxetine did not demonstrate barbiturate-like (depressant) abuse potential.  
769 While Cymbalta has not been systematically studied in humans for its potential for abuse, there was  
770 no indication of drug-seeking behavior in the clinical trials. However, it is not possible to predict on the  
771 basis of premarketing experience the extent to which a CNS active drug will be misused, diverted, and/or  
772 abused once marketed. Consequently, physicians should carefully evaluate patients for a history of drug  
773 abuse and follow such patients closely, observing them for signs of misuse or abuse of Cymbalta  
774 (e.g., development of tolerance, incrementation of dose, drug-seeking behavior).

**775 9.3 Dependence**

776 In drug dependence studies, duloxetine did not demonstrate dependence-producing potential in rats.

**777 10 OVERDOSAGE****778 10.1 Signs and Symptoms**

779 In postmarketing experience, fatal outcomes have been reported for acute overdoses, primarily with  
780 mixed overdoses, but also with duloxetine only, at doses as low as 1000 mg. Signs and symptoms of  
781 overdose (duloxetine alone or with mixed drugs) included somnolence, coma, serotonin syndrome,  
782 seizures, syncope, tachycardia, hypotension, hypertension, and vomiting.

**783 10.2 Management of Overdose**

784 There is no specific antidote to Cymbalta, but if serotonin syndrome ensues, specific treatment  
785 (such as with cyproheptadine and/or temperature control) may be considered. In case of acute overdose,  
786 treatment should consist of those general measures employed in the management of overdose with any  
787 drug.

788 An adequate airway, oxygenation, and ventilation should be assured, and cardiac rhythm and vital  
789 signs should be monitored. Induction of emesis is not recommended. Gastric lavage with a large-bore  
790 orogastric tube with appropriate airway protection, if needed, may be indicated if performed soon after  
791 ingestion or in symptomatic patients.

792 Activated charcoal may be useful in limiting absorption of duloxetine from the gastrointestinal  
 793 tract. Administration of activated charcoal has been shown to decrease AUC and  $C_{max}$  by an average  
 794 of one-third, although some subjects had a limited effect of activated charcoal. Due to the large volume of  
 795 distribution of this drug, forced diuresis, dialysis, hemoperfusion, and exchange transfusion are unlikely to  
 796 be beneficial.

797 In managing overdose, the possibility of multiple drug involvement should be considered. A  
 798 specific caution involves patients who are taking or have recently taken Cymbalta and might ingest  
 799 excessive quantities of a TCA. In such a case, decreased clearance of the parent tricyclic and/or its active  
 800 metabolite may increase the possibility of clinically significant sequelae and extend the time needed for  
 801 close medical observation [see *Warnings and Precautions (5.4) and Drug Interactions (7)*]. The physician  
 802 should consider contacting a poison control center for additional information on the treatment of any  
 803 overdose. Telephone numbers for certified poison control centers are listed in the *Physicians' Desk*  
 804 *Reference (PDR)*.

## 805 11 DESCRIPTION

806 Cymbalta<sup>®</sup> (duloxetine hydrochloride) is a selective serotonin and norepinephrine reuptake  
 807 inhibitor (SSNRI) for oral administration. Its chemical designation is (+)-(S)-N-methyl-γ-(1-naphthoxy)-  
 808 2-thiophenpropylamine hydrochloride. The empirical formula is  $C_{18}H_{19}NOS \cdot HCl$ , which corresponds to a  
 809 molecular weight of 333.88. The structural formula is:  
 810

811 Duloxetine hydrochloride is a white to slightly brownish white solid, which is slightly soluble in  
 812 water.  
 813

814 Each capsule contains enteric-coated pellets of 22.4, 33.7, or 67.3 mg of duloxetine hydrochloride  
 815 equivalent to 20, 30, or 60 mg of duloxetine, respectively. These enteric-coated pellets are designed to  
 816 prevent degradation of the drug in the acidic environment of the stomach. Inactive ingredients include  
 817 FD&C Blue No. 2, gelatin, hypromellose, hydroxypropyl methylcellulose acetate succinate, sodium lauryl  
 818 sulfate, sucrose, sugar spheres, talc, titanium dioxide, and triethyl citrate. The 20 and 60 mg capsules also  
 819 contain iron oxide yellow.

## 820 12 CLINICAL PHARMACOLOGY

### 821 12.1 Mechanism of Action

822 Although the exact mechanisms of the antidepressant, central pain inhibitory and anxiolytic actions  
 823 of duloxetine in humans are unknown, these actions are believed to be related to its potentiation of  
 824 serotonergic and noradrenergic activity in the CNS.

### 825 12.2 Pharmacodynamics

826 Preclinical studies have shown that duloxetine is a potent inhibitor of neuronal serotonin and  
 827 norepinephrine reuptake and a less potent inhibitor of dopamine reuptake. Duloxetine has no significant  
 828 affinity for dopaminergic, adrenergic, cholinergic, histaminergic, opioid, glutamate, and GABA receptors  
 829 *in vitro*. Duloxetine does not inhibit monoamine oxidase (MAO).

830 Cymbalta is in a class of drugs known to affect urethral resistance. If symptoms of urinary  
 831 hesitation develop during treatment with Cymbalta, consideration should be given to the possibility that  
 832 they might be drug-related.

### 833 12.3 Pharmacokinetics

834 Duloxetine has an elimination half-life of about 12 hours (range 8 to 17 hours) and its  
 835 pharmacokinetics are dose proportional over the therapeutic range. Steady-state plasma concentrations are

836 typically achieved after 3 days of dosing. Elimination of duloxetine is mainly through hepatic metabolism  
837 involving two P450 isozymes, CYP1A2 and CYP2D6.

838 Absorption and Distribution — Orally administered duloxetine hydrochloride is well absorbed.  
839 There is a median 2 hour lag until absorption begins ( $T_{lag}$ ), with maximal plasma concentrations ( $C_{max}$ ) of  
840 duloxetine occurring 6 hours post dose. Food does not affect the  $C_{max}$  of duloxetine, but delays the time to  
841 reach peak concentration from 6 to 10 hours and it marginally decreases the extent of absorption (AUC) by  
842 about 10%. There is a 3 hour delay in absorption and a one-third increase in apparent clearance of  
843 duloxetine after an evening dose as compared to a morning dose.

844 The apparent volume of distribution averages about 1640 L. Duloxetine is highly bound (>90%) to  
845 proteins in human plasma, binding primarily to albumin and  $\alpha_1$ -acid glycoprotein. The interaction between  
846 duloxetine and other highly protein bound drugs has not been fully evaluated. Plasma protein binding of  
847 duloxetine is not affected by renal or hepatic impairment.

848 Metabolism and Elimination — Biotransformation and disposition of duloxetine in humans have  
849 been determined following oral administration of  $^{14}C$ -labeled duloxetine. Duloxetine comprises about 3%  
850 of the total radiolabeled material in the plasma, indicating that it undergoes extensive metabolism to  
851 numerous metabolites. The major biotransformation pathways for duloxetine involve oxidation of the  
852 naphthyl ring followed by conjugation and further oxidation. Both CYP1A2 and CYP2D6 catalyze the  
853 oxidation of the naphthyl ring *in vitro*. Metabolites found in plasma include 4-hydroxy duloxetine  
854 glucuronide and 5-hydroxy, 6-methoxy duloxetine sulfate. Many additional metabolites have been  
855 identified in urine, some representing only minor pathways of elimination. Only trace (<1% of the dose)  
856 amounts of unchanged duloxetine are present in the urine. Most (about 70%) of the duloxetine dose appears  
857 in the urine as metabolites of duloxetine; about 20% is excreted in the feces. Duloxetine undergoes  
858 extensive metabolism, but the major circulating metabolites have not been shown to contribute significantly  
859 to the pharmacologic activity of duloxetine.

## 860 13 NONCLINICAL TOXICOLOGY

### 861 13.1 Carcinogenesis, Mutagenesis, and Impairment of Fertility

862 Carcinogenesis — Duloxetine was administered in the diet to mice and rats for 2 years.

863 In female mice receiving duloxetine at 140 mg/kg/day (11 times the maximum recommended  
864 human dose [MRHD, 60 mg/day] and 6 times the human dose of 120 mg/day on a  $mg/m^2$  basis), there was  
865 an increased incidence of hepatocellular adenomas and carcinomas. The no-effect dose was 50 mg/kg/day  
866 (4 times the MRHD and 2 times the human dose of 120 mg/day on a  $mg/m^2$  basis). Tumor incidence was  
867 not increased in male mice receiving duloxetine at doses up to 100 mg/kg/day (8 times the MRHD and  
868 4 times the human dose of 120 mg/day on a  $mg/m^2$  basis).

869 In rats, dietary doses of duloxetine up to 27 mg/kg/day in females (4 times the MRHD and 2 times  
870 the human dose of 120 mg/day on a  $mg/m^2$  basis) and up to 36 mg/kg/day in males (6 times the MRHD and  
871 3 times the human dose of 120 mg/day on a  $mg/m^2$  basis) did not increase the incidence of tumors.

872 Mutagenesis — Duloxetine was not mutagenic in the *in vitro* bacterial reverse mutation  
873 assay (Ames test) and was not clastogenic in an *in vivo* chromosomal aberration test in mouse bone marrow  
874 cells. Additionally, duloxetine was not genotoxic in an *in vitro* mammalian forward gene mutation assay in  
875 mouse lymphoma cells or in an *in vitro* unscheduled DNA synthesis (UDS) assay in primary rat  
876 hepatocytes, and did not induce sister chromatid exchange in Chinese hamster bone marrow *in vivo*.

877 Impairment of Fertility — Duloxetine administered orally to either male or female rats prior to and  
878 throughout mating at doses up to 45 mg/kg/day (7 times the maximum recommended human dose of  
879 60 mg/day and 4 times the human dose of 120 mg/day on a  $mg/m^2$  basis) did not alter mating or fertility.

## 880 14 CLINICAL STUDIES

### 881 14.1 Major Depressive Disorder

882 The efficacy of Cymbalta as a treatment for depression was established in 4 randomized,  
883 double-blind, placebo-controlled, fixed-dose studies in adult outpatients (18 to 83 years) meeting DSM-IV  
884 criteria for major depression. In 2 studies, patients were randomized to Cymbalta 60 mg once daily  
885 (N=123 and N=128, respectively) or placebo (N=122 and N=139, respectively) for 9 weeks; in the  
886 third study, patients were randomized to Cymbalta 20 or 40 mg twice daily (N=86 and N=91, respectively)  
887 or placebo (N=89) for 8 weeks; in the fourth study, patients were randomized to Cymbalta 40 or 60 mg  
888 twice daily (N=95 and N=93, respectively) or placebo (N=93) for 8 weeks. There is no evidence that doses  
889 greater than 60 mg/day confer additional benefits.

890 In all 4 studies, Cymbalta demonstrated superiority over placebo as measured by improvement in  
891 the 17-item Hamilton Depression Rating Scale (HAMD-17) total score.

892 In all of these clinical studies, analyses of the relationship between treatment outcome and age,  
893 gender, and race did not suggest any differential responsiveness on the basis of these patient characteristics.

894 In another study, 533 patients meeting DSM-IV criteria for MDD received Cymbalta 60 mg  
895 once daily during an initial 12-week open-label treatment phase. Two hundred and seventy-eight patients  
896 who responded to open label treatment (defined as meeting the following criteria at weeks 10 and 12: a  
897 HAMD-17 total score  $\leq 9$ , Clinical Global Impressions of Severity (CGI-S)  $\leq 2$ , and not meeting the DSM-  
898 IV criteria for MDD) were randomly assigned to continuation of Cymbalta at the same dose (N=136) or to  
899 placebo (N=142) for 6 months. Patients on Cymbalta experienced a statistically significantly longer time to  
900 relapse of depression than did patients on placebo. Relapse was defined as an increase in the CGI-S score  
901 of  $\geq 2$  points compared with that obtained at week 12, as well as meeting the DSM-IV criteria for MDD at 2  
902 consecutive visits at least 2 weeks apart, where the 2-week temporal criterion had to be satisfied at only the  
903 second visit. The effectiveness of Cymbalta in hospitalized patients with major depressive disorder has not  
904 been studied.

#### 905 **14.2 Generalized Anxiety Disorder**

906 The efficacy of Cymbalta in the treatment of generalized anxiety disorder (GAD) was established  
907 in 1 fixed-dose randomized, double-blind, placebo-controlled trial and 2 flexible-dose randomized,  
908 double-blind, placebo-controlled trials in adult outpatients between 18 and 83 years of age meeting the  
909 DSM-IV criteria for GAD.

910 In 1 flexible-dose study and in the fixed-dose study, the starting dose was 60 mg once daily where  
911 down titration to 30 mg once daily was allowed for tolerability reasons before increasing it to 60 mg  
912 once daily. Fifteen percent of patients were down titrated. One flexible-dose study had a starting dose of  
913 30 mg once daily for 1 week before increasing it to 60 mg once daily.

914 The 2 flexible-dose studies involved dose titration with Cymbalta doses ranging from 60 mg  
915 once daily to 120 mg once daily (N=168 and N=162) compared to placebo (N=159 and N=161) over a  
916 10-week treatment period. The mean dose for completers at endpoint in the flexible-dose studies was  
917 104.75 mg/day. The fixed-dose study evaluated Cymbalta doses of 60 mg once daily (N=168) and 120 mg  
918 once daily (N=170) compared to placebo (N=175) over a 9-week treatment period. While a 120 mg/day  
919 dose was shown to be effective, there is no evidence that doses greater than 60 mg/day confer additional  
920 benefit.

921 In all 3 studies, Cymbalta demonstrated superiority over placebo as measured by greater  
922 improvement in the Hamilton Anxiety Scale (HAM-A) total score and by the Sheehan Disability  
923 Scale (SDS) global functional impairment score. The SDS is a widely used and well-validated scale that  
924 measures the extent emotional symptoms disrupt patient functioning in 3 life domains: work/school, social  
925 life/leisure activities, and family life/home responsibilities.

926 Subgroup analyses did not indicate that there were any differences in treatment outcomes as a  
927 function of age or gender.

#### 928 **14.3 Diabetic Peripheral Neuropathic Pain**

929 The efficacy of Cymbalta for the management of neuropathic pain associated with diabetic  
930 peripheral neuropathy was established in 2 randomized, 12-week, double-blind, placebo-controlled,  
931 fixed-dose studies in adult patients having diabetic peripheral neuropathic pain for at least 6 months.  
932 Study 1 and 2 enrolled a total of 791 patients of whom 592 (75%) completed the studies. Patients enrolled  
933 had Type I or II diabetes mellitus with a diagnosis of painful distal symmetrical sensorimotor  
934 polyneuropathy for at least 6 months. The patients had a baseline pain score of  $\geq 4$  on an 11-point scale  
935 ranging from 0 (no pain) to 10 (worst possible pain). Patients were permitted up to 4 g of acetaminophen  
936 per day as needed for pain, in addition to Cymbalta. Patients recorded their pain daily in a diary.

937 Both studies compared Cymbalta 60 mg once daily or 60 mg twice daily with placebo. Study 1  
938 additionally compared Cymbalta 20 mg with placebo. A total of 457 patients (342 Cymbalta, 115 placebo)  
939 were enrolled in Study 1 and a total of 334 patients (226 Cymbalta, 108 placebo) were enrolled in Study 2.  
940 Treatment with Cymbalta 60 mg one or two times a day statistically significantly improved the endpoint  
941 mean pain scores from baseline and increased the proportion of patients with at least a 50% reduction in  
942 pain score from baseline. For various degrees of improvement in pain from baseline to study endpoint,  
943 Figures 1 and 2 show the fraction of patients achieving that degree of improvement. The figures are  
944 cumulative, so that patients whose change from baseline is, for example, 50%, are also included at every

945 level of improvement below 50%. Patients who did not complete the study were assigned 0% improvement.  
 946 Some patients experienced a decrease in pain as early as week 1, which persisted throughout the study.  
 947

948 **Figure 1: Percentage of Patients Achieving Various Levels of Pain Relief**  
 949 **as Measured by 24-Hour Average Pain Severity - Study 1**  
 950

951 **Figure 2: Percentage of Patients Achieving Various Levels of Pain Relief**  
 952 **as Measured by 24-Hour Average Pain Severity - Study 2**  
 953

954 **14.4 Fibromyalgia**

955 The efficacy of Cymbalta for the management of fibromyalgia was established in two randomized,  
 956 double-blind, placebo-controlled, fixed-dose studies in adult patients meeting the American College of  
 957 Rheumatology criteria for fibromyalgia (a history of widespread pain for 3 months, and pain present at 11  
 958 or more of the 18 specific tender point sites). Study 1 was three months in duration and enrolled female  
 959 patients only. Study 2 was six months in duration and enrolled male and female patients. Approximately  
 960 25% of participants had a comorbid diagnosis of major depressive disorder (MDD). Study 1 and 2 enrolled

961 a total of 874 patients of whom 541 (62%) completed the studies. The patients had a baseline pain score of  
 962 6.5 on an 11-point scale ranging from 0 (no pain) to 10 (worse possible pain).

963 Both studies compared Cymbalta 60 mg once daily or 120 mg daily (given in divided doses in  
 964 Study 1 and as a single daily dose in Study 2) with placebo. Study 2 additionally compared Cymbalta 20  
 965 mg with placebo during the initial three months of a six-month study. A total of 354 patients (234  
 966 Cymbalta, 120 placebo) were enrolled in Study 1 and a total of 520 patients (376 Cymbalta, 144 placebo)  
 967 were enrolled in Study 2 (5% male, 95% female). Treatment with Cymbalta 60 mg or 120 mg daily  
 968 statistically significantly improved the endpoint mean pain scores from baseline and increase the proportion  
 969 of patients with at least a 50% reduction in pain score from baseline. Pain reduction was observed in  
 970 patients both with and without comorbid MDD. However, the degree of pain reduction may be greater in  
 971 patients with comorbid MDD. For various degrees of improvement in pain from baseline to study endpoint,  
 972 Figures 3 and 4 show the fraction of patients achieving that degree of improvement. The figures are  
 973 cumulative so that patients whose change from baseline is, for example, 50%, are also included at every  
 974 level of improvement below 50%. Patients who did not complete the study were assigned 0% improvement.  
 975 Some patients experienced a decrease in pain as early as week 1, which persisted throughout the study.  
 976 Improvement was also demonstrated on measures of function (Fibromyalgia Impact Questionnaires) and  
 977 patient global impression of change (PGI). Neither study demonstrated a benefit of 120 mg compared to 60  
 978 mg, and a higher dose was associated with more adverse reactions and premature discontinuations of  
 979 treatment.  
 980

981  
 982  
 983  
 984  
 985  
 986

987  
988 **Figure 4: Percentage of Patients Achieving Various Levels of Pain Relief as Measured by 24-Hour**  
989 **Average Pain Severity - Study 2**  
990

991 Additionally, the benefit of up-titration in non-responders to Cymbalta at 60 mg/day was evaluated  
992 in a separate study. Patients were initially treated with Cymbalta 60 mg once daily for eight weeks in open-  
993 label fashion. Subsequently, completers of this phase were randomized to double-blind treatment with  
994 Cymbalta at either 60 mg once daily or 120 mg once daily. Those patients who were considered non-  
995 responders, where response was defined as at least a 30% reduction in pain score from baseline at the end  
996 of the 8-week treatment, were no more likely to meet response criteria at the end of 60 weeks of treatment  
997 if blindly titrated to Cymbalta 120 mg as compared to those who were blindly continued on Cymbalta 60  
998 mg.

999 **16 HOW SUPPLIED/STORAGE AND HANDLING**

1000 **16.1 How Supplied**

1001 Cymbalta is available as delayed release capsules in the following strengths, colors, imprints, and  
1002 presentations:

Features	Strengths		
	20 mg*	30 mg*	60 mg*
Body color	Opaque green	Opaque white	Opaque green
Cap color	Opaque green	Opaque blue	Opaque blue

1005

1006 **16.2 Storage**

1007 Store at 25°C (77°F); excursions permitted to 15-30°C (59-86°F) [see USP Controlled Room  
1008 Temperature].

1009 **17 PATIENT COUNSELING INFORMATION**

1010 See FDA-approved Medication Guide

1011 **17.1 Information on Medication Guide**

1012 Prescribers or other health professionals should inform patients, their families, and their caregivers  
1013 about the benefits and risks associated with treatment with Cymbalta and should counsel them in its  
1014 appropriate use. A patient Medication Guide About Using Antidepressants in Children and Teenagers is  
1015 available for Cymbalta. The prescriber or health professional should instruct patients, their families, and  
1016 their caregivers to read the Medication Guide and should assist them in understanding its contents. Patients  
1017 should be given the opportunity to discuss the contents of the Medication Guide and to obtain answers to  
1018 any questions they may have. The complete text of the Medication Guide is reprinted at the end of this  
1019 document.

1020 Patients should be advised of the following issues and asked to alert their prescriber if these occur  
1021 while taking Cymbalta.

1022 **17.2 Clinical Worsening and Suicide Risk**

1023 Patients, their families, and their caregivers should be encouraged to be alert to the emergence of  
1024 anxiety, agitation, panic attacks, insomnia, irritability, hostility, aggressiveness, impulsivity, akathisia  
1025 (psychomotor restlessness), hypomania, mania, other unusual changes in behavior, worsening of  
1026 depression, and suicidal ideation, especially early during antidepressant treatment and when the dose is  
1027 adjusted up or down. Families and caregivers of patients should be advised to observe for the emergence of  
1028 such symptoms on a day-to-day basis, since changes may be abrupt. Such symptoms should be reported to  
1029 the patient's prescriber or health professional, especially if they are severe, abrupt in onset, or were not part  
1030 of the patient's presenting symptoms. Symptoms such as these may be associated with an increased risk for  
1031 suicidal thinking and behavior and indicate a need for very close monitoring and possibly changes in the  
1032 medication [see *Boxed Warning, and Warnings and Precautions (5.1)*].

1033 **17.3 Medication Administration**

1034 Cymbalta should be swallowed whole and should not be chewed or crushed, nor should the capsule  
1035 be opened and its contents be sprinkled on food or mixed with liquids. All of these might affect the enteric  
1036 coating.

1037 **17.4 Continuing the Therapy Prescribed**

1038 While patients may notice improvement with Cymbalta therapy in 1 to 4 weeks, they should be  
1039 advised to continue therapy as directed.

1040 **17.5 Abnormal Bleeding**

1041 Patients should be cautioned about the concomitant use of duloxetine and NSAIDs, aspirin,  
1042 warfarin, or other drugs that affect coagulation since combined use of psychotropic drugs that interfere with  
1043 serotonin reuptake and these agents has been associated with an increased risk of bleeding [see *Warnings  
1044 and Precautions (5.5)*].

1045 **17.6 Concomitant Medications**

1046 Patients should be advised to inform their physicians if they are taking, or plan to take, any  
1047 prescription or over-the-counter medications, since there is a potential for interactions [see *Dosage and  
1048 Administration (2.5), Contraindications (4.1), Warnings and Precautions (5.4 and 5.10), and Drug  
1049 Interactions (7)*].

1050 **17.7 Serotonin Syndrome**

1051 Patients should be cautioned about the risk of serotonin syndrome with the concomitant use of  
1052 Cymbalta and triptans, tramadol or other serotonergic agents [see *Warnings and Precautions (5.4) and  
1053 Drug Interactions (7.14)*].

1054 **17.8 Pregnancy and Breast Feeding**

1055 Patients should be advised to notify their physician if they  
1056 • become pregnant during therapy

- 1057 • intend to become pregnant during therapy  
1058 • are breast feeding [*see Dosage and Administration (2.3) and Use in Specific Populations (8.1,*  
1059 *8.2, and 8.3)*].

1060 **17.9 Alcohol**

1061 Although Cymbalta does not increase the impairment of mental and motor skills caused by alcohol,  
1062 use of Cymbalta concomitantly with heavy alcohol intake may be associated with severe liver injury. For  
1063 this reason, Cymbalta should ordinarily not be prescribed for patients with substantial alcohol use [*see*  
1064 *Warnings and Precautions (5.2) and Drug Interactions (7.16)*].

1065 **17.10 Orthostatic Hypotension and Syncope**

1066 Patients should be advised of the risk of orthostatic hypotension and syncope, especially during the  
1067 period of initial use and subsequent dose escalation, and in association with the use of concomitant drugs  
1068 that might potentiate the orthostatic effect of duloxetine [*see Warnings and Precautions (5.3)*].

1069 **17.11 Interference with Psychomotor Performance**

1070 Any psychoactive drug may impair judgment, thinking, or motor skills. Although in controlled  
1071 studies Cymbalta has not been shown to impair psychomotor performance, cognitive function, or memory,  
1072 it may be associated with sedation and dizziness. Therefore, patients should be cautioned about operating  
1073 hazardous machinery including automobiles, until they are reasonably certain that Cymbalta therapy does  
1074 not affect their ability to engage in such activities.
