

HIGHLIGHTS OF PRESCRIBING INFORMATION

These highlights do not include all the information needed to use AVANDIA safely and effectively. See full prescribing information for AVANDIA.

AVANDIA (rosiglitazone maleate) tablets
Initial U.S. Approval: 1999

WARNING: CONGESTIVE HEART FAILURE
See full prescribing information for complete boxed warning.

- **Thiazolidinediones, including rosiglitazone, cause or exacerbate congestive heart failure in some patients (5.1). After initiation of AVANDIA, and after dose increases, observe patients carefully for signs and symptoms of heart failure (including excessive, rapid weight gain; dyspnea; and/or edema). If these signs and symptoms develop, the heart failure should be managed according to current standards of care. Furthermore, discontinuation or dose reduction of AVANDIA must be considered.**
- **AVANDIA is not recommended in patients with symptomatic heart failure. Initiation of AVANDIA in patients with established NYHA Class III or IV heart failure is contraindicated. (4, 5.1)**

-----**INDICATIONS AND USAGE**-----

AVANDIA is a thiazolidinedione antidiabetic agent indicated as an adjunct to diet and exercise to improve glycemic control in adults with type 2 diabetes mellitus. (1)

Important Limitations of Use:

- AVANDIA should not be used in patients with type 1 diabetes mellitus or for the treatment of diabetic ketoacidosis. (1)
- Coadministration of AVANDIA and insulin is not recommended. (1, 5.1, 5.2)

-----**DOSAGE AND ADMINISTRATION**-----

- Start at 4 mg daily in single or divided doses; do not exceed 8 mg daily. (2)
- Dose increases should be accompanied by careful monitoring for adverse events related to fluid retention. (2)
- Do not initiate AVANDIA if the patient exhibits clinical evidence of active liver disease or increased serum transaminase levels. (2.1)

-----**DOSAGE FORMS AND STRENGTHS**-----

Pentagonal, film-coated tablets in the following strengths: 2 mg and 4 mg (3)

-----**CONTRAINDICATIONS**-----

- Initiation in patients with established NYHA Class III or IV heart failure. (4)

- Hypersensitivity to rosiglitazone or any of the product’s ingredients. (4)

-----**WARNINGS and PRECAUTIONS**-----

- Fluid retention, which may exacerbate or lead to heart failure, may occur. Combination use with insulin and use in congestive heart failure NYHA Class I and II may increase risk of other cardiovascular effects. (5.1)
- Meta-analysis of 52 mostly short-term trials suggested a potential risk of ischemic cardiovascular (CV) events relative to placebo, not confirmed in a long-term CV outcome trial versus metformin or sulfonylurea. (5.2)
- Dose-related edema (5.3) and weight gain (5.4) may occur.
- Measure liver enzymes prior to initiation and periodically thereafter. Do not initiate therapy in patients with increased baseline liver enzyme levels (ALT >2.5X upper limit of normal). Discontinue therapy if ALT levels remain >3X the upper limit of normal or if jaundice is observed. (5.5)
- Macular edema has been reported. (5.6)
- Increased incidence of bone fracture was observed in long-term trials. (5.7)
- Dose-related decreases in hemoglobin and hemocrit have occurred. (5.8)
- When used in combination with other hypoglycemic agents, a dose reduction of the concomitant agent may be necessary to reduce the risk of hypoglycemia. (5.9)

-----**ADVERSE REACTIONS**-----

Common adverse reactions (>5%) reported in clinical trials without regard to causality were upper respiratory tract infection, injury, and headache. (6.1)

To report SUSPECTED ADVERSE REACTIONS, contact GlaxoSmithKline at 1-888-825-5249 or FDA at 1-800-FDA-1088 or www.fda.gov/medwatch.

-----**DRUG INTERACTIONS**-----

Inhibitors of CYP2C8 (e.g., gemfibrozil) may increase rosiglitazone levels; inducers of CYP2C8 (e.g., rifampin) may decrease rosiglitazone levels. (7.1)

-----**USE IN SPECIFIC POPULATIONS**-----

- **Pregnancy:** No adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit justifies the potential risk to the fetus. (8.1)
- **Nursing Mothers:** Discontinue drug or nursing. (8.3)
- Safety and effectiveness in children younger than 18 years have not been established. (8.4)

See **17** for **PATIENT COUNSELING INFORMATION** and **Medication Guide**.

*Sections or subsections omitted from the full prescribing information are not listed.

1 FULL PRESCRIBING INFORMATION

2 **WARNING: CONGESTIVE HEART FAILURE**

- 3 • **Thiazolidinediones, including rosiglitazone, cause or exacerbate congestive heart failure**
4 **in some patients [see Warnings and Precautions (5.1)]. After initiation of AVANDIA[®],**
5 **and after dose increases, observe patients carefully for signs and symptoms of heart**
6 **failure (including excessive, rapid weight gain; dyspnea; and/or edema). If these signs**
7 **and symptoms develop, the heart failure should be managed according to current**
8 **standards of care. Furthermore, discontinuation or dose reduction of AVANDIA must**
9 **be considered.**
- 10 • **AVANDIA is not recommended in patients with symptomatic heart failure. Initiation of**
11 **AVANDIA in patients with established NYHA Class III or IV heart failure is**
12 **contraindicated. [See Contraindications (4), Warnings and Precautions (5.1).]**

13 **1 INDICATIONS AND USAGE**

14 AVANDIA is a thiazolidinedione antidiabetic agent indicated as an adjunct to diet and exercise
15 to improve glycemic control in adults with type 2 diabetes mellitus.

16 **Important Limitations of Use:**

- 17 • Due to its mechanism of action, AVANDIA is active only in the presence of endogenous
18 insulin. Therefore, AVANDIA should not be used in patients with type 1 diabetes mellitus or
19 for the treatment of diabetic ketoacidosis.
- 20 • The coadministration of AVANDIA and insulin is not recommended [see Warnings and
21 *Precautions (5.1)*].

22 **2 DOSAGE AND ADMINISTRATION**

23 AVANDIA may be administered at a starting dose of 4 mg either as a single daily dose or in 2
24 divided doses. For patients who respond inadequately following 8 to 12 weeks of treatment, as
25 determined by reduction in fasting plasma glucose (FPG), the dose may be increased to 8 mg
26 daily. Increases in the dose of AVANDIA should be accompanied by careful monitoring for
27 adverse events related to fluid retention [see *Boxed Warning, Warnings and Precautions (5.1)*].
28 AVANDIA may be taken with or without food.

29 The total daily dose of AVANDIA should not exceed 8 mg.

30 Patients receiving AVANDIA in combination with other hypoglycemic agents may be at risk for
31 hypoglycemia, and a reduction in the dose of the concomitant agent may be necessary.

32 **2.1 Specific Patient Populations**

33 Renal Impairment

34 No dosage adjustment is necessary when AVANDIA is used as monotherapy in patients with
35 renal impairment. Since metformin is contraindicated in such patients, concomitant
36 administration of metformin and AVANDIA is also contraindicated in patients with renal
37 impairment.

38 Hepatic Impairment

39 Liver enzymes should be measured prior to initiating treatment with AVANDIA. Therapy with
40 AVANDIA should not be initiated if the patient exhibits clinical evidence of active liver disease
41 or increased serum transaminase levels (ALT >2.5X upper limit of normal at start of therapy).
42 After initiation of AVANDIA, liver enzymes should be monitored periodically per the clinical
43 judgment of the healthcare professional. [See Warnings and Precautions (5.5), Clinical
44 Pharmacology (12.3).]

45 Pediatric

46 Data are insufficient to recommend pediatric use of AVANDIA [see Use in Specific Populations
47 (8.4)].

48 **3 DOSAGE FORMS AND STRENGTHS**

49 Pentagonal film-coated TILTAB[®] tablet contains rosiglitazone as the maleate as follows:

- 50 • 2 mg – pink, debossed with GSK on one side and 2 on the other
- 51 • 4 mg – orange, debossed with GSK on one side and 4 on the other

52 **4 CONTRAINDICATIONS**

- 53 • Initiation of AVANDIA in patients with established New York Heart Association (NYHA)
54 Class III or IV heart failure is contraindicated [see Boxed Warning].
- 55 • Use in patients with a history of a hypersensitivity reaction to rosiglitazone or any of the
56 product's ingredients.

57 **5 WARNINGS AND PRECAUTIONS**

58 **5.1 Cardiac Failure**

59 AVANDIA, like other thiazolidinediones, alone or in combination with other antidiabetic agents,
60 can cause fluid retention, which may exacerbate or lead to heart failure. Patients should be
61 observed for signs and symptoms of heart failure. If these signs and symptoms develop, the heart
62 failure should be managed according to current standards of care. Furthermore, discontinuation
63 or dose reduction of rosiglitazone must be considered [see Boxed Warning].

64 Patients with congestive heart failure (CHF) NYHA Class I and II treated with AVANDIA have

65 an increased risk of cardiovascular events. A 52-week, double-blind, placebo-controlled,
 66 echocardiographic trial was conducted in 224 patients with type 2 diabetes mellitus and NYHA
 67 Class I or II CHF (ejection fraction \leq 45%) on background antidiabetic and CHF therapy. An
 68 independent committee conducted a blinded evaluation of fluid-related events (including
 69 congestive heart failure) and cardiovascular hospitalizations according to predefined criteria
 70 (adjudication). Separate from the adjudication, other cardiovascular adverse events were reported
 71 by investigators. Although no treatment difference in change from baseline of ejection fractions
 72 was observed, more cardiovascular adverse events were observed following treatment with
 73 AVANDIA compared with placebo during the 52-week trial (Table 1).

74 **Table 1. Emergent Cardiovascular Adverse Events in Patients with Congestive Heart**
 75 **Failure (NYHA Class I and II) Treated with AVANDIA or Placebo (in Addition to**
 76 **Background Antidiabetic and CHF Therapy)**

Events	AVANDIA N = 110 n (%)	Placebo N = 114 n (%)
Adjudicated		
Cardiovascular deaths	5 (5%)	4 (4%)
CHF worsening	7 (6%)	4 (4%)
– with overnight hospitalization	5 (5%)	4 (4%)
– without overnight hospitalization	2 (2%)	0 (0%)
New or worsening edema	28 (25%)	10 (9%)
New or worsening dyspnea	29 (26%)	19 (17%)
Increases in CHF medication	36 (33%)	20 (18%)
Cardiovascular hospitalization ^a	21 (19%)	15 (13%)
Investigator-reported, non-adjudicated		
Ischemic adverse events	10 (9%)	5 (4%)
– Myocardial infarction	5 (5%)	2 (2%)
– Angina	6 (5%)	3 (3%)

77 ^a Includes hospitalization for any cardiovascular reason.

78 In a long-term, cardiovascular outcome trial (RECORD) in patients with type 2 diabetes [see
 79 *Adverse Reactions (6.1)*], the incidence of heart failure was higher in patients treated with
 80 AVANDIA [2.7% (61/2,220) compared with active control 1.3% (29/2,227), HR 2.10 (95% CI:
 81 1.35, 3.27)].

82 Initiation of AVANDIA in patients with established NYHA Class III or IV heart failure is
 83 contraindicated. AVANDIA is not recommended in patients with symptomatic heart failure. [See
 84 *Boxed Warning.*]

85 Patients experiencing acute coronary syndromes have not been studied in controlled clinical
 86 trials. In view of the potential for development of heart failure in patients having an acute

87 coronary event, initiation of AVANDIA is not recommended for patients experiencing an acute
88 coronary event, and discontinuation of AVANDIA during this acute phase should be considered.

89 Patients with NYHA Class III and IV cardiac status (with or without CHF) have not been studied
90 in controlled clinical trials. AVANDIA is not recommended in patients with NYHA Class III and
91 IV cardiac status.

92 Congestive Heart Failure during Coadministration of AVANDIA with Insulin

93 In trials in which AVANDIA was added to insulin, AVANDIA increased the risk of congestive
94 heart failure. Coadministration of AVANDIA and insulin is not recommended. [*See Indications*
95 *and Usage (1), Warnings and Precautions (5.2).*]

96 In 7 controlled, randomized, double-blind trials which had durations from 16 to 26 weeks and
97 which were included in a meta-analysis [*see Warnings and Precautions (5.2)*], patients with type
98 2 diabetes mellitus were randomized to coadministration of AVANDIA and insulin (N = 1,018)
99 or insulin (N = 815). In these 7 trials, AVANDIA was added to insulin. These trials included
100 patients with long-standing diabetes (median duration of 12 years) and a high prevalence of pre-
101 existing medical conditions, including peripheral neuropathy, retinopathy, ischemic heart
102 disease, vascular disease, and congestive heart failure. The total number of patients with
103 emergent congestive heart failure was 23 (2.3%) and 8 (1.0%) in the group receiving AVANDIA
104 plus insulin and the insulin group, respectively.

105 Heart Failure in Observational Studies of Elderly Diabetic Patients Comparing AVANDIA 106 with Pioglitazone

107 Three observational studies in elderly diabetic patients (age 65 years and older) found that
108 AVANDIA statistically significantly increased the risk of hospitalized heart failure compared
109 with use of pioglitazone. One other observational study in patients with a mean age of 54 years,
110 which also included an analysis in a subpopulation of patients >65 years of age, found no
111 statistically significant increase in emergency department visits or hospitalization for heart
112 failure in patients treated with AVANDIA compared with pioglitazone in the older subgroup.

113 **5.2 Major Adverse Cardiovascular Events**

114 Data from long-term, prospective, randomized, controlled clinical trials of AVANDIA versus
115 metformin or sulfonylureas, particularly a cardiovascular outcome trial (RECORD), observed no
116 difference in overall mortality or in major adverse cardiovascular events (MACE) and its
117 components. A meta-analysis of mostly short-term trials suggested an increased risk for
118 myocardial infarction with AVANDIA compared with placebo.

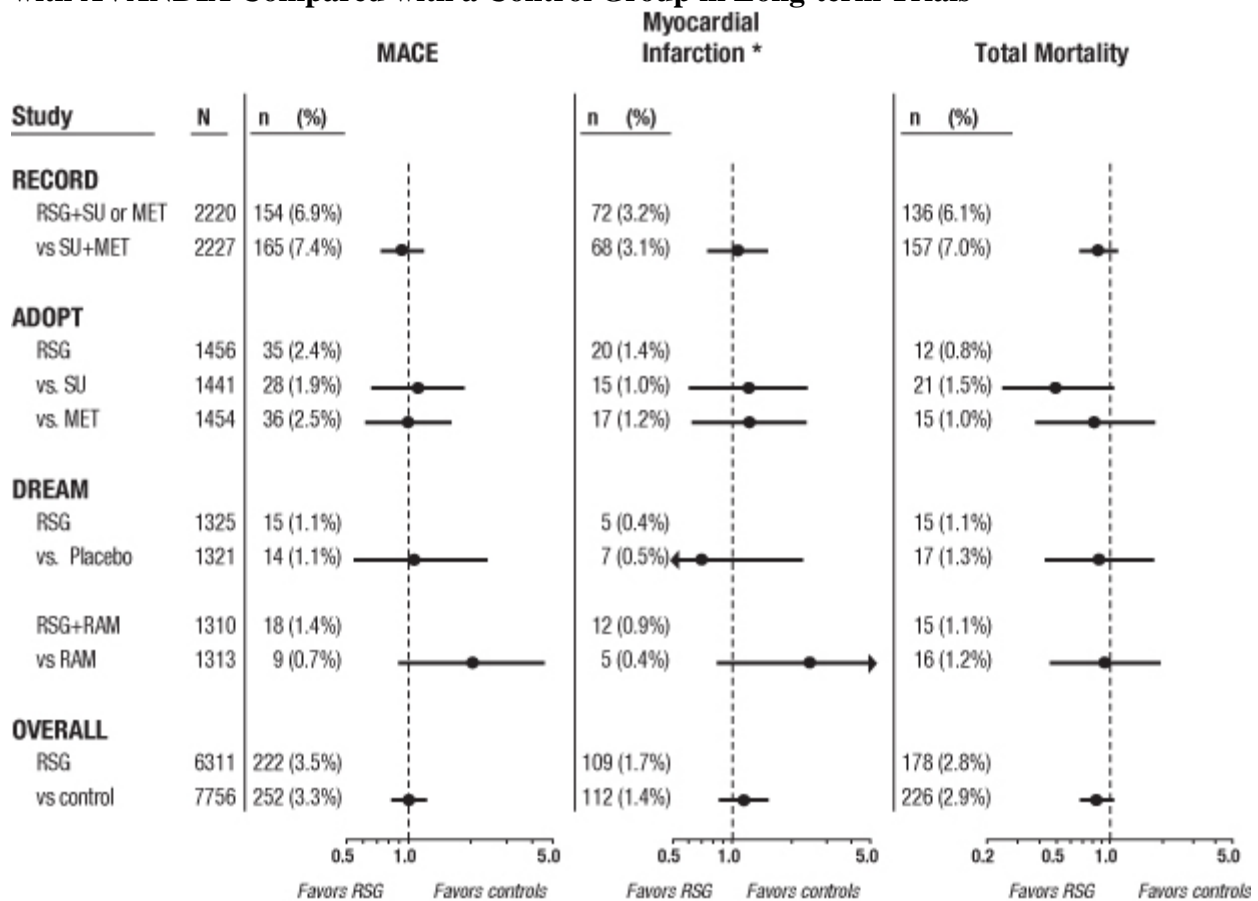

119 Cardiovascular Events in Large, Long-term, Prospective, Randomized, Controlled Trials 120 of AVANDIA

121 RECORD, a prospectively designed cardiovascular outcome trial (mean follow-up 5.5 years;
122 4,447 patients), compared the addition of AVANDIA to metformin or a sulfonylurea (N = 2,220)

123 with a control group of metformin plus sulfonylurea (N = 2,227) in patients with type 2 diabetes
124 [see *Adverse Reactions (6.1)*]. Non-inferiority was demonstrated for the primary endpoint,
125 cardiovascular hospitalization or cardiovascular death, for AVANDIA compared with control
126 [HR 0.99 (95% CI: 0.85, 1.16)] demonstrating no overall increased risk in cardiovascular
127 morbidity or mortality. The hazard ratios for total mortality and MACE were consistent with the
128 primary endpoint and the 95% CI similarly excluded a 20% increase in risk for AVANDIA. The
129 hazard ratios for the components of MACE were 0.72 (95% CI: 0.49, 1.06) for stroke, 1.14 (95%
130 CI: 0.80, 1.63) for myocardial infarction, and 0.84 (95% CI: 0.59, 1.18) for cardiovascular death.

131 The results of RECORD are consistent with the findings of 2 earlier long-term, prospective,
132 randomized, controlled clinical trials (each trial >3 years' duration; total of 9,620 patients) (see
133 Figure 1). In patients with impaired glucose tolerance (DREAM trial), although the incidence of
134 cardiovascular events was higher among subjects who were randomized to AVANDIA in
135 combination with ramipril than among subjects randomized to ramipril alone, no statistically
136 significant differences were observed for MACE and its components between AVANDIA and
137 placebo. In patients with type 2 diabetes who were initiating oral agent monotherapy (ADOPT
138 trial), no statistically significant differences were observed for MACE and its components
139 between AVANDIA and metformin or a sulfonylurea.

140 **Figure 1. Hazard Ratios for the Risk of MACE, Myocardial Infarction, and Total Mortality**
 141 **with AVANDIA Compared with a Control Group in Long-term Trials**

RSG = rosiglitazone; SU = sulfonylurea; MET = metformin; RAM = ramipril
 * Myocardial infarction includes fatal and non-fatal MI plus sudden death

142
 143 **Cardiovascular Events in a Group of 52 Clinical Trials**

144 In a meta-analysis of 52 double-blind, randomized, controlled clinical trials designed to assess
 145 glucose-lowering efficacy in type 2 diabetes (mean duration 6 months), a statistically significant
 146 increased risk of myocardial infarction with AVANDIA versus pooled comparators was
 147 observed (0.4% versus 0.3%; OR 1.8, [95% CI: 1.03, 3.25]). A statistically non-significant
 148 increased risk of MACE was observed with AVANDIA versus pooled comparators (OR 1.44,
 149 95% CI: 0.95, 2.20). In the placebo-controlled trials, a statistically significant increased risk of
 150 myocardial infarction (0.4% versus 0.2%, OR 2.23 [95% CI: 1.14, 4.64]) and statistically non-
 151 significant increased risk of MACE (0.7% versus 0.5%, OR 1.53 [95% CI: 0.94, 2.54]) with
 152 AVANDIA were observed. In the active-controlled trials, there was no increased risk of
 153 myocardial infarction or MACE.

154 **Mortality in Observational Studies of AVANDIA Compared with Pioglitazone**

155 Three observational studies in elderly diabetic patients (age 65 years and older) found that
 156 AVANDIA statistically significantly increased the risk of all-cause mortality compared with use

157 of pioglitazone. One observational study in patients with a mean age of 54 years found no
158 difference in all-cause mortality between patients treated with AVANDIA compared with
159 pioglitazone and reported similar results in the subpopulation of patients >65 years of age. One
160 additional small, prospective, observational study found no statistically significant differences
161 for CV mortality and all-cause mortality in patients treated with AVANDIA compared with
162 pioglitazone.

163 **5.3 Edema**

164 AVANDIA should be used with caution in patients with edema. In a clinical trial in healthy
165 volunteers who received 8 mg of AVANDIA once daily for 8 weeks, there was a statistically
166 significant increase in median plasma volume compared with placebo.

167 Since thiazolidinediones, including rosiglitazone, can cause fluid retention, which can exacerbate
168 or lead to congestive heart failure, AVANDIA should be used with caution in patients at risk for
169 heart failure. Patients should be monitored for signs and symptoms of heart failure [*see Boxed*
170 *Warning, Warnings and Precautions (5.1), Patient Counseling Information (17)*].

171 In controlled clinical trials of patients with type 2 diabetes, mild to moderate edema was reported
172 in patients treated with AVANDIA, and may be dose related. Patients with ongoing edema were
173 more likely to have adverse events associated with edema if started on combination therapy with
174 insulin and AVANDIA [*see Adverse Reactions (6.1)*].

175 **5.4 Weight Gain**

176 Dose-related weight gain was seen with AVANDIA alone and in combination with other
177 hypoglycemic agents (Table 2). The mechanism of weight gain is unclear but probably involves
178 a combination of fluid retention and fat accumulation.

179 In postmarketing experience, there have been reports of unusually rapid increases in weight and
180 increases in excess of that generally observed in clinical trials. Patients who experience such
181 increases should be assessed for fluid accumulation and volume-related events such as excessive
182 edema and congestive heart failure [*see Boxed Warning*].

183 **Table 2. Weight Changes (kg) from Baseline at Endpoint during Clinical Trials**

Monotherapy	Duration	Control Group		AVANDIA 4 mg	AVANDIA 8 mg
			Median (25 th , 75 th percentiles)	Median (25 th , 75 th percentiles)	Median (25 th , 75 th percentiles)
	26 weeks	placebo	-0.9 (-2.8, 0.9) N = 210	1.0 (-0.9, 3.6) N = 436	3.1 (1.1, 5.8) N = 439
	52 weeks	sulfonylurea	2.0 (0, 4.0) N = 173	2.0 (-0.6, 4.0) N = 150	2.6 (0, 5.3) N = 157
Combination Therapy					
Sulfonylurea	24-26 weeks	sulfonylurea	0 (-1.0, 1.3) N = 1,155	2.2 (0.5, 4.0) N = 613	3.5 (1.4, 5.9) N = 841
Metformin	26 weeks	metformin	-1.4 (-3.2, 0.2) N = 175	0.8 (-1.0, 2.6) N = 100	2.1 (0, 4.3) N = 184
Insulin	26 weeks	insulin	0.9 (-0.5, 2.7) N = 162	4.1 (1.4, 6.3) N = 164	5.4 (3.4, 7.3) N = 150
Sulfonylurea + metformin	26 weeks	sulfonylurea + metformin	0.2 (-1.2, 1.6) N = 272	2.5 (0.8, 4.6) N = 275	4.5 (2.4, 7.3) N = 276

184 In a 4- to 6-year, monotherapy, comparative trial (ADOPT) in patients recently diagnosed with
 185 type 2 diabetes not previously treated with antidiabetic medication [see *Clinical Studies (14.1)*],
 186 the median weight change (25th, 75th percentiles) from baseline at 4 years was 3.5 kg (0.0, 8.1)
 187 for AVANDIA, 2.0 kg (-1.0, 4.8) for glyburide, and -2.4 kg (-5.4, 0.5) for metformin.

188 In a 24-week trial in pediatric patients aged 10 to 17 years treated with AVANDIA 4 to 8 mg
 189 daily, a median weight gain of 2.8 kg (25th, 75th percentiles: 0.0, 5.8) was reported.

190 **5.5 Hepatic Effects**

191 Liver enzymes should be measured prior to the initiation of therapy with AVANDIA in all
 192 patients and periodically thereafter per the clinical judgment of the healthcare professional.
 193 Therapy with AVANDIA should not be initiated in patients with increased baseline liver enzyme
 194 levels (ALT >2.5X upper limit of normal). Patients with mildly elevated liver enzymes (ALT
 195 levels ≤2.5X upper limit of normal) at baseline or during therapy with AVANDIA should be
 196 evaluated to determine the cause of the liver enzyme elevation. Initiation of, or continuation of,
 197 therapy with AVANDIA in patients with mild liver enzyme elevations should proceed with
 198 caution and include close clinical follow-up, including liver enzyme monitoring, to determine if
 199 the liver enzyme elevations resolve or worsen. If at any time ALT levels increase to >3X the
 200 upper limit of normal in patients on therapy with AVANDIA, liver enzyme levels should be
 201 rechecked as soon as possible. If ALT levels remain >3X the upper limit of normal, therapy with

202 AVANDIA should be discontinued.

203 If any patient develops symptoms suggesting hepatic dysfunction, which may include
204 unexplained nausea, vomiting, abdominal pain, fatigue, anorexia and/or dark urine, liver
205 enzymes should be checked. The decision whether to continue the patient on therapy with
206 AVANDIA should be guided by clinical judgment pending laboratory evaluations. If jaundice is
207 observed, drug therapy should be discontinued. [See *Adverse Reactions* (6.2, 6.3).]

208 **5.6 Macular Edema**

209 Macular edema has been reported in postmarketing experience in some diabetic patients who
210 were taking AVANDIA or another thiazolidinedione. Some patients presented with blurred
211 vision or decreased visual acuity, but some patients appear to have been diagnosed on routine
212 ophthalmologic examination. Most patients had peripheral edema at the time macular edema was
213 diagnosed. Some patients had improvement in their macular edema after discontinuation of their
214 thiazolidinedione. Patients with diabetes should have regular eye exams by an ophthalmologist,
215 per the Standards of Care of the American Diabetes Association. Additionally, any diabetic who
216 reports any kind of visual symptom should be promptly referred to an ophthalmologist,
217 regardless of the patient's underlying medications or other physical findings. [See *Adverse*
218 *Reactions* (6.1).]

219 **5.7 Fractures**

220 Long-term trials (ADOPT and RECORD) show an increased incidence of bone fracture in
221 patients, particularly female patients, taking AVANDIA [see *Adverse Reactions* (6.1)]. This
222 increased incidence was noted after the first year of treatment and persisted during the course of
223 the trial. The majority of the fractures in the women who received AVANDIA occurred in the
224 upper arm, hand, and foot. These sites of fracture are different from those usually associated with
225 postmenopausal osteoporosis (e.g., hip or spine). Other trials suggest that this risk may also
226 apply to men, although the risk of fracture among women appears higher than that among men.
227 The risk of fracture should be considered in the care of patients treated with AVANDIA, and
228 attention given to assessing and maintaining bone health according to current standards of care.

229 **5.8 Hematologic Effects**

230 Decreases in mean hemoglobin and hematocrit occurred in a dose-related fashion in adult
231 patients treated with AVANDIA [see *Adverse Reactions* (6.2)]. The observed changes may be
232 related to the increased plasma volume observed with treatment with AVANDIA.

233 **5.9 Diabetes and Blood Glucose Control**

234 Patients receiving AVANDIA in combination with other hypoglycemic agents may be at risk for
235 hypoglycemia, and a reduction in the dose of the concomitant agent may be necessary.

236 Periodic fasting blood glucose and HbA1c measurements should be performed to monitor
237 therapeutic response.

238 **5.10 Ovulation**

239 Therapy with AVANDIA, like other thiazolidinediones, may result in ovulation in some
240 premenopausal anovulatory women. As a result, these patients may be at an increased risk for
241 pregnancy while taking AVANDIA [see *Use in Specific Populations (8.1)*]. Thus, adequate
242 contraception in premenopausal women should be recommended. This possible effect has not
243 been specifically investigated in clinical trials; therefore, the frequency of this occurrence is not
244 known.

245 Although hormonal imbalance has been seen in preclinical studies [see *Nonclinical Toxicology*
246 *(13.1)*], the clinical significance of this finding is not known. If unexpected menstrual
247 dysfunction occurs, the benefits of continued therapy with AVANDIA should be reviewed.

248 **6 ADVERSE REACTIONS**

249 The following adverse reactions are discussed in more detail elsewhere in the labeling:

- 250 • Cardiac Failure [see *Warnings and Precautions (5.1)*]
- 251 • Major Adverse Cardiovascular Events [see *Warnings and Precautions (5.2)*]
- 252 • Edema [see *Warnings and Precautions (5.3)*]
- 253 • Weight Gain [see *Warnings and Precautions (5.4)*]
- 254 • Hepatic Effects [see *Warnings and Precautions (5.5)*]
- 255 • Macular Edema [see *Warnings and Precautions (5.6)*]
- 256 • Fractures [see *Warnings and Precautions (5.7)*]
- 257 • Hematologic Effects [see *Warnings and Precautions (5.8)*]
- 258 • Ovulation [see *Warnings and Precautions (5.10)*]

259 **6.1 Clinical Trial Experience**

260 Because clinical trials are conducted under widely varying conditions, adverse reaction rates
261 observed in the clinical trials of a drug cannot be directly compared with rates in the clinical
262 trials of another drug and may not reflect the rates observed in practice.

263 Adult

264 In clinical trials, approximately 9,900 patients with type 2 diabetes have been treated with
265 AVANDIA.

266 *Short-term Trials of AVANDIA as Monotherapy and in Combination with Other*
267 *Hypoglycemic Agents:* The incidence and types of adverse events reported in short-term
268 clinical trials of AVANDIA as monotherapy are shown in Table 3.

269 **Table 3. Adverse Events ($\geq 5\%$ in any Treatment Group) Reported by Patients in Short-**
 270 **term^a Double-blind Clinical Trials with AVANDIA as Monotherapy**

Preferred Term	AVANDIA Monotherapy N = 2,526 %	Placebo N = 601 %	Metformin N = 225 %	Sulfonylureas^b N = 626 %
Upper respiratory tract infection	9.9	8.7	8.9	7.3
Injury	7.6	4.3	7.6	6.1
Headache	5.9	5.0	8.9	5.4
Back pain	4.0	3.8	4.0	5.0
Hyperglycemia	3.9	5.7	4.4	8.1
Fatigue	3.6	5.0	4.0	1.9
Sinusitis	3.2	4.5	5.3	3.0
Diarrhea	2.3	3.3	15.6	3.0
Hypoglycemia	0.6	0.2	1.3	5.9

271 ^a Short-term trials ranged from 8 weeks to 1 year.

272 ^b Includes patients receiving glyburide (N = 514), gliclazide (N = 91), or glipizide (N = 21).

273 Overall, the types of adverse reactions without regard to causality reported when AVANDIA was
 274 used in combination with a sulfonylurea or metformin were similar to those during monotherapy
 275 with AVANDIA.

276 Events of anemia and edema tended to be reported more frequently at higher doses, and were
 277 generally mild to moderate in severity and usually did not require discontinuation of treatment
 278 with AVANDIA.

279 In double-blind trials, anemia was reported in 1.9% of patients receiving AVANDIA as
 280 monotherapy compared with 0.7% on placebo, 0.6% on sulfonylureas, and 2.2% on metformin.
 281 Reports of anemia were greater in patients treated with a combination of AVANDIA and
 282 metformin (7.1%) and with a combination of AVANDIA and a sulfonylurea plus metformin
 283 (6.7%) compared with monotherapy with AVANDIA or in combination with a sulfonylurea
 284 (2.3%). Lower pre-treatment hemoglobin/hematocrit levels in patients enrolled in the metformin
 285 combination clinical trials may have contributed to the higher reporting rate of anemia in these
 286 trials [see *Adverse Reactions* (6.2)].

287 In clinical trials, edema was reported in 4.8% of patients receiving AVANDIA as monotherapy
 288 compared with 1.3% on placebo, 1.0% on sulfonylureas, and 2.2% on metformin. The reporting
 289 rate of edema was higher for AVANDIA 8 mg in sulfonylurea combinations (12.4%) compared
 290 with other combinations, with the exception of insulin. Edema was reported in 14.7% of patients
 291 receiving AVANDIA in the insulin combination trials compared with 5.4% on insulin alone.
 292 Reports of new onset or exacerbation of congestive heart failure occurred at rates of 1% for

293 insulin alone, and 2% (4 mg) and 3% (8 mg) for insulin in combination with AVANDIA [see
294 *Boxed Warning, Warnings and Precautions (5.1)*].

295 In controlled combination therapy trials with sulfonylureas, mild to moderate hypoglycemic
296 symptoms, which appear to be dose related, were reported. Few patients were withdrawn for
297 hypoglycemia (<1%) and few episodes of hypoglycemia were considered to be severe (<1%).
298 Hypoglycemia was the most frequently reported adverse event in the fixed-dose insulin
299 combination trials, although few patients withdrew for hypoglycemia (4 of 408 for AVANDIA
300 plus insulin and 1 of 203 for insulin alone). Rates of hypoglycemia, confirmed by capillary blood
301 glucose concentration ≤50 mg/dL, were 6% for insulin alone and 12% (4 mg) and 14% (8 mg)
302 for insulin in combination with AVANDIA. [See *Warnings and Precautions (5.9)*.]

303 *Long-term Trial of AVANDIA as Monotherapy:* A 4- to 6-year trial (ADOPT) compared the
304 use of AVANDIA (n = 1,456), glyburide (n = 1,441), and metformin (n = 1,454) as monotherapy
305 in patients recently diagnosed with type 2 diabetes who were not previously treated with
306 antidiabetic medication. Table 4 presents adverse reactions without regard to causality; rates are
307 expressed per 100 patient-years (PY) exposure to account for the differences in exposure to trial
308 medication across the 3 treatment groups.

309 In ADOPT, fractures were reported in a greater number of women treated with AVANDIA
310 (9.3%, 2.7/100 patient-years) compared with glyburide (3.5%, 1.3/100 patient-years) or
311 metformin (5.1%, 1.5/100 patient-years). The majority of the fractures in the women who
312 received rosiglitazone were reported in the upper arm, hand, and foot. [See *Warnings and*
313 *Precautions (5.7)*.] The observed incidence of fractures for male patients was similar among the
314 3 treatment groups.

315 **Table 4. On-Therapy Adverse Events [≥5 Events/100 Patient-Years (PY)] in any Treatment**
316 **Group Reported in a 4- to 6-Year Clinical Trial of AVANDIA as Monotherapy (ADOPT)**

Preferred Term	AVANDIA N = 1,456 PY = 4,954	Glyburide N = 1,441 PY = 4,244	Metformin N = 1,454 PY = 4,906
Nasopharyngitis	6.3	6.9	6.6
Back pain	5.1	4.9	5.3
Arthralgia	5.0	4.8	4.2
Hypertension	4.4	6.0	6.1
Upper respiratory tract infection	4.3	5.0	4.7
Hypoglycemia	2.9	13.0	3.4
Diarrhea	2.5	3.2	6.8

317 *Long-term Trial of AVANDIA as Combination Therapy (RECORD):* RECORD
318 (Rosiglitazone Evaluated for Cardiac Outcomes and Regulation of Glycemia in Diabetes) was a
319 multicenter, randomized, open-label, non-inferiority trial in subjects with type 2 diabetes

320 inadequately controlled on maximum doses of metformin or sulfonylurea (glyburide, gliclazide,
 321 or glimepiride) to compare the time to reach the combined cardiovascular endpoint of
 322 cardiovascular death or cardiovascular hospitalization between patients randomized to the
 323 addition of AVANDIA versus metformin or sulfonylurea. The trial included patients who have
 324 failed metformin or sulfonylurea monotherapy; those who failed metformin (n = 2,222) were
 325 randomized to receive either AVANDIA as add-on therapy (n = 1,117) or add-on sulfonylurea
 326 (n = 1,105), and those who failed sulfonylurea (n = 2,225) were randomized to receive either
 327 AVANDIA as add-on therapy (n = 1,103) or add-on metformin (n = 1,122). Patients were treated
 328 to target HbA1c ≤7% throughout the trial.

329 The mean age of patients in this trial was 58 years, 52% were male, and the mean duration of
 330 follow-up was 5.5 years. AVANDIA demonstrated non-inferiority to active control for the
 331 primary endpoint of cardiovascular hospitalization or cardiovascular death (HR 0.99, 95% CI:
 332 0.85-1.16). There were no significant differences between groups for secondary endpoints with
 333 the exception of congestive heart failure (Table 5). The incidence of congestive heart failure was
 334 significantly greater among patients randomized to AVANDIA.

335 **Table 5. Cardiovascular (CV) Outcomes for the RECORD Trial**

Primary Endpoint	AVANDIA N = 2,220	Active Control N = 2,227	Hazard Ratio	95% CI
CV death or CV hospitalization	321	323	0.99	0.85-1.16
Secondary Endpoint				
All-cause death	136	157	0.86	0.68-1.08
CV death	60	71	0.84	0.59-1.18
Myocardial infarction	64	56	1.14	0.80-1.63
Stroke	46	63	0.72	0.49-1.06
CV death, myocardial infarction, or stroke	154	165	0.93	0.74-1.15
Heart failure	61	29	2.10	1.35-3.27

336 There was an increased incidence of bone fracture for subjects randomized to AVANDIA in
 337 addition to metformin or sulfonylurea compared with those randomized to metformin plus
 338 sulfonylurea (8.3% versus 5.3%) [see *Warnings and Precautions (5.7)*]. The majority of
 339 fractures were reported in the upper limbs and distal lower limbs. The risk of fracture appeared
 340 to be higher in females relative to control (11.5% versus 6.3%) than in males relative to control
 341 (5.3% versus 4.3%). Additional data are necessary to determine whether there is an increased
 342 risk of fracture in males after a longer period of follow-up.

343 Pediatric

344 AVANDIA has been evaluated for safety in a single, active-controlled trial of pediatric patients
 345 with type 2 diabetes in which 99 were treated with AVANDIA and 101 were treated with
 346 metformin. The most common adverse reactions (>10%) without regard to causality for either

347 AVANDIA or metformin were headache (17% versus 14%), nausea (4% versus 11%),
348 nasopharyngitis (3% versus 12%), and diarrhea (1% versus 13%). In this trial, one case of
349 diabetic ketoacidosis was reported in the metformin group. In addition, there were 3 patients in
350 the rosiglitazone group who had FPG of approximately 300 mg/dL, 2+ ketonuria, and an
351 elevated anion gap.

352 **6.2 Laboratory Abnormalities**

353 Hematologic

354 Decreases in mean hemoglobin and hematocrit occurred in a dose-related fashion in adult
355 patients treated with AVANDIA (mean decreases in individual trials as much as 1.0 g/dL
356 hemoglobin and as much as 3.3% hematocrit). The changes occurred primarily during the first
357 3 months following initiation of therapy with AVANDIA or following a dose increase in
358 AVANDIA. The time course and magnitude of decreases were similar in patients treated with a
359 combination of AVANDIA and other hypoglycemic agents or monotherapy with AVANDIA.
360 Pre-treatment levels of hemoglobin and hematocrit were lower in patients in metformin
361 combination trials and may have contributed to the higher reporting rate of anemia. In a single
362 trial in pediatric patients, decreases in hemoglobin and hematocrit (mean decreases of 0.29 g/dL
363 and 0.95%, respectively) were reported. Small decreases in hemoglobin and hematocrit have also
364 been reported in pediatric patients treated with AVANDIA. White blood cell counts also
365 decreased slightly in adult patients treated with AVANDIA. Decreases in hematologic
366 parameters may be related to increased plasma volume observed with treatment with
367 AVANDIA.

368 Lipids

369 Changes in serum lipids have been observed following treatment with AVANDIA in adults [*see*
370 *Clinical Pharmacology (12.2)*]. Small changes in serum lipid parameters were reported in
371 children treated with AVANDIA for 24 weeks.

372 Serum Transaminase Levels

373 In pre-approval clinical trials in 4,598 patients treated with AVANDIA (3,600 patient-years of
374 exposure) and in a long-term 4- to 6-year trial in 1,456 patients treated with AVANDIA (4,954
375 patient-years exposure), there was no evidence of drug-induced hepatotoxicity.

376 In pre-approval controlled trials, 0.2% of patients treated with AVANDIA had elevations in ALT
377 >3X the upper limit of normal compared with 0.2% on placebo and 0.5% on active comparators.
378 The ALT elevations in patients treated with AVANDIA were reversible. Hyperbilirubinemia was
379 found in 0.3% of patients treated with AVANDIA compared with 0.9% treated with placebo and
380 1% in patients treated with active comparators. In pre-approval clinical trials, there were no cases
381 of idiosyncratic drug reactions leading to hepatic failure. [*See Warnings and Precautions (5.5).*]

382 In the 4- to 6-year ADOPT trial, patients treated with AVANDIA (4,954 patient-years exposure),
383 glyburide (4,244 patient-years exposure), or metformin (4,906 patient-years exposure), as

384 monotherapy, had the same rate of ALT increase to >3X upper limit of normal (0.3 per 100
385 patient-years exposure).

386 In the RECORD trial, patients randomized to AVANDIA in addition to metformin or
387 sulfonylurea (10,849 patient-years exposure) and to metformin plus sulfonylurea (10,209 patient-
388 years exposure) had a rate of ALT increase to $\geq 3X$ upper limit of normal of approximately 0.2
389 and 0.3 per 100 patient-years exposure, respectively.

390 **6.3 Postmarketing Experience**

391 In addition to adverse reactions reported from clinical trials, the events described below have
392 been identified during post-approval use of AVANDIA. Because these events are reported
393 voluntarily from a population of unknown size, it is not possible to reliably estimate their
394 frequency or to always establish a causal relationship to drug exposure.

395 In patients receiving thiazolidinedione therapy, serious adverse events with or without a fatal
396 outcome, potentially related to volume expansion (e.g., congestive heart failure, pulmonary
397 edema, and pleural effusions) have been reported [*see Boxed Warning, Warnings and*
398 *Precautions (5.1)*].

399 There are postmarketing reports with AVANDIA of hepatitis, hepatic enzyme elevations to 3 or
400 more times the upper limit of normal, and hepatic failure with and without fatal outcome,
401 although causality has not been established.

402 There are postmarketing reports with AVANDIA of rash, pruritus, urticaria, angioedema,
403 anaphylactic reaction, Stevens-Johnson syndrome [*see Contraindications (4)*], and new onset or
404 worsening diabetic macular edema with decreased visual acuity [*see Warnings and Precautions*
405 *(5.6)*].

406 **7 DRUG INTERACTIONS**

407 **7.1 CYP2C8 Inhibitors and Inducers**

408 An inhibitor of CYP2C8 (e.g., gemfibrozil) may increase the AUC of rosiglitazone and an
409 inducer of CYP2C8 (e.g., rifampin) may decrease the AUC of rosiglitazone. Therefore, if an
410 inhibitor or an inducer of CYP2C8 is started or stopped during treatment with rosiglitazone,
411 changes in diabetes treatment may be needed based upon clinical response. [*See Clinical*
412 *Pharmacology (12.4)*].

413 **8 USE IN SPECIFIC POPULATIONS**

414 **8.1 Pregnancy**

415 Pregnancy Category C.

416 All pregnancies have a background risk of birth defects, loss, or other adverse outcome
417 regardless of drug exposure. This background risk is increased in pregnancies complicated by

418 hyperglycemia and may be decreased with good metabolic control. It is essential for patients
419 with diabetes or history of gestational diabetes to maintain good metabolic control before
420 conception and throughout pregnancy. Careful monitoring of glucose control is essential in such
421 patients. Most experts recommend that insulin monotherapy be used during pregnancy to
422 maintain blood glucose levels as close to normal as possible.

423 Human Data

424 Rosiglitazone has been reported to cross the human placenta and be detectable in fetal tissue. The
425 clinical significance of these findings is unknown. There are no adequate and well-controlled
426 trials in pregnant women. AVANDIA should be used during pregnancy only if the potential
427 benefit justifies the potential risk to the fetus.

428 Animal Studies

429 There was no effect on implantation or the embryo with rosiglitazone treatment during early
430 pregnancy in rats, but treatment during mid-late gestation was associated with fetal death and
431 growth retardation in both rats and rabbits. Teratogenicity was not observed at doses up to
432 3 mg/kg in rats and 100 mg/kg in rabbits (approximately 20 and 75 times human AUC at the
433 maximum recommended human daily dose, respectively). Rosiglitazone caused placental
434 pathology in rats (3 mg/kg/day). Treatment of rats during gestation through lactation reduced
435 litter size, neonatal viability, and postnatal growth, with growth retardation reversible after
436 puberty. For effects on the placenta, embryo/fetus, and offspring, the no-effect dose was
437 0.2 mg/kg/day in rats and 15 mg/kg/day in rabbits. These no-effect levels are approximately
438 4 times human AUC at the maximum recommended human daily dose. Rosiglitazone reduced
439 the number of uterine implantations and live offspring when juvenile female rats were treated at
440 40 mg/kg/day from 27 days of age through to sexual maturity (approximately 68 times human
441 AUC at the maximum recommended daily dose). The no-effect level was 2 mg/kg/day
442 (approximately 4 times human AUC at the maximum recommended daily dose). There was no
443 effect on pre- or post-natal survival or growth.

444 **8.2 Labor and Delivery**

445 The effect of rosiglitazone on labor and delivery in humans is not known.

446 **8.3 Nursing Mothers**

447 Drug-related material was detected in milk from lactating rats. It is not known whether
448 AVANDIA is excreted in human milk. Because many drugs are excreted in human milk, a
449 decision should be made whether to discontinue nursing or to discontinue AVANDIA, taking
450 into account the importance of the drug to the mother.

451 **8.4 Pediatric Use**

452 After placebo run-in including diet counseling, children with type 2 diabetes mellitus, aged 10 to
453 17 years and with a baseline mean body mass index (BMI) of 33 kg/m², were randomized to

454 treatment with 2 mg twice daily of AVANDIA (n = 99) or 500 mg twice daily of metformin
 455 (n = 101) in a 24-week, double-blind clinical trial. As expected, FPG decreased in patients naïve
 456 to diabetes medication (n = 104) and increased in patients withdrawn from prior medication
 457 (usually metformin) (n = 90) during the run-in period. After at least 8 weeks of treatment, 49%
 458 of patients treated with AVANDIA and 55% of metformin-treated patients had their dose
 459 doubled if FPG >126 mg/dL. For the overall intent-to-treat population, at Week 24, the mean
 460 change from baseline in HbA1c was -0.14% with AVANDIA and -0.49% with metformin. There
 461 was an insufficient number of patients in this trial to establish statistically whether these
 462 observed mean treatment effects were similar or different. Treatment effects differed for patients
 463 naïve to therapy with antidiabetic drugs and for patients previously treated with antidiabetic
 464 therapy (Table 6).

465 **Table 6. Week 24 FPG and HbA1c Change from Baseline Last-Observation—carried**
 466 **Forward in Children with Baseline HbA1c >6.5%**

Parameter	Naïve Patients		Previously-treated Patients	
	Metformin N = 40	Rosiglitazone N = 45	Metformin N = 43	Rosiglitazone N = 32
FPG (mg/dL)				
Baseline (mean)	170	165	221	205
Change from baseline (mean)	-21	-11	-33	-5
Adjusted treatment difference ^a (rosiglitazone–metformin) ^b (95% CI)		8 (-15, 30)		21 (-9, 51)
% of patients with ≥30 mg/dL decrease from baseline	43%	27%	44%	28%
HbA1c (%)				
Baseline (mean)	8.3	8.2	8.8	8.5
Change from baseline (mean)	-0.7	-0.5	-0.4	0.1
Adjusted treatment difference ^a (rosiglitazone–metformin) ^b (95% CI)		0.2 (-0.6, 0.9)		0.5 (-0.2, 1.3)
% of patients with ≥0.7% decrease from baseline	63%	52%	54%	31%

467 ^a Change from baseline means are least squares means adjusting for baseline HbA1c, gender,
 468 and region.

469 ^b Positive values for the difference favor metformin.

470 Treatment differences depended on baseline BMI or weight such that the effects of AVANDIA
 471 and metformin appeared more closely comparable among heavier patients. The median weight
 472 gain was 2.8 kg with rosiglitazone and 0.2 kg with metformin [see *Warnings and Precautions*
 473 (5.4)]. Fifty-four percent of patients treated with rosiglitazone and 32% of patients treated with

474 metformin gained ≥ 2 kg, and 33% of patients treated with rosiglitazone and 7% of patients
475 treated with metformin gained ≥ 5 kg on trial.

476 Adverse events observed in this trial are described in *Adverse Reactions (6.1)*.

477 **Figure 2. Mean HbA1c over Time in a 24-Week Trial of AVANDIA and Metformin in**
478 **Pediatric Patients — Drug-Naïve Subgroup**

479

480 8.5 Geriatric Use

481 Results of the population pharmacokinetic analysis showed that age does not significantly affect
482 the pharmacokinetics of rosiglitazone [see *Clinical Pharmacology (12.3)*]. Therefore, no dosage
483 adjustments are required for the elderly. In controlled clinical trials, no overall differences in
484 safety and effectiveness between older (≥ 65 years) and younger (< 65 years) patients were
485 observed.

486 10 OVERDOSAGE

487 Limited data are available with regard to overdosage in humans. In clinical trials in volunteers,
488 AVANDIA has been administered at single oral doses of up to 20 mg and was well tolerated. In
489 the event of an overdose, appropriate supportive treatment should be initiated as dictated by the
490 patient's clinical status.

491 11 DESCRIPTION

492 AVANDIA (rosiglitazone maleate) is an oral antidiabetic agent which acts primarily by
493 increasing insulin sensitivity. AVANDIA improves glycemic control while reducing circulating
494 insulin levels.

495 Rosiglitazone maleate is not chemically or functionally related to the sulfonylureas, the
496 biguanides, or the alpha-glucosidase inhibitors.

497 Chemically, rosiglitazone maleate is (\pm)-5-[[4-[2-(methyl-2-
498 pyridinylamino)ethoxy]phenyl]methyl]-2,4-thiazolidinedione, (Z)-2-butenedioate (1:1) with a
499 molecular weight of 473.52 (357.44 free base). The molecule has a single chiral center and is
500 present as a racemate. Due to rapid interconversion, the enantiomers are functionally
501 indistinguishable. The structural formula of rosiglitazone maleate is:

502
503 The molecular formula is $C_{18}H_{19}N_3O_3S \cdot C_4H_4O_4$. Rosiglitazone maleate is a white to off-white
504 solid with a melting point range of 122° to $123^\circ C$. The pKa values of rosiglitazone maleate are
505 6.8 and 6.1. It is readily soluble in ethanol and a buffered aqueous solution with pH of 2.3;
506 solubility decreases with increasing pH in the physiological range.

507 Each pentagonal film-coated TILTAB tablet contains rosiglitazone maleate equivalent to
508 rosiglitazone, 2 mg or 4 mg, for oral administration. Inactive ingredients are: hypromellose 2910,
509 lactose monohydrate, magnesium stearate, microcrystalline cellulose, polyethylene glycol 3000,
510 sodium starch glycolate, titanium dioxide, triacetin, and 1 or more of the following: synthetic red
511 and yellow iron oxides and talc.

512 12 CLINICAL PHARMACOLOGY

513 12.1 Mechanism of Action

514 Rosiglitazone, a member of the thiazolidinedione class of antidiabetic agents, improves glycemic
515 control by improving insulin sensitivity. Rosiglitazone is a highly selective and potent agonist for
516 the peroxisome proliferator-activated receptor-gamma (PPAR γ). In humans, PPAR receptors are
517 found in key target tissues for insulin action such as adipose tissue, skeletal muscle, and liver.
518 Activation of PPAR γ nuclear receptors regulates the transcription of insulin-responsive genes
519 involved in the control of glucose production, transport, and utilization. In addition, PPAR γ -
520 responsive genes also participate in the regulation of fatty acid metabolism.

521 Insulin resistance is a common feature characterizing the pathogenesis of type 2 diabetes. The
522 antidiabetic activity of rosiglitazone has been demonstrated in animal models of type 2 diabetes
523 in which hyperglycemia and/or impaired glucose tolerance is a consequence of insulin resistance
524 in target tissues. Rosiglitazone reduces blood glucose concentrations and reduces
525 hyperinsulinemia in the ob/ob obese mouse, db/db diabetic mouse, and fa/fa fatty Zucker rat.

526 In animal models, the antidiabetic activity of rosiglitazone was shown to be mediated by
527 increased sensitivity to insulin's action in the liver, muscle, and adipose tissues. Pharmacological
528 studies in animal models indicate that rosiglitazone inhibits hepatic gluconeogenesis. The
529 expression of the insulin-regulated glucose transporter GLUT-4 was increased in adipose tissue.

530 Rosiglitazone did not induce hypoglycemia in animal models of type 2 diabetes and/or impaired
531 glucose tolerance.

532 **12.2 Pharmacodynamics**

533 Patients with lipid abnormalities were not excluded from clinical trials of AVANDIA. In all 26-
534 week controlled trials, across the recommended dose range, AVANDIA as monotherapy was
535 associated with increases in total cholesterol, LDL, and HDL, and decreases in free fatty acids.
536 These changes were statistically significantly different from placebo or glyburide controls (Table
537 7).

538 Increases in LDL occurred primarily during the first 1 to 2 months of therapy with AVANDIA
539 and LDL levels remained elevated above baseline throughout the trials. In contrast, HDL
540 continued to rise over time. As a result, the LDL/HDL ratio peaked after 2 months of therapy and
541 then appeared to decrease over time. Because of the temporal nature of lipid changes, the 52-
542 week, glyburide-controlled trial is most pertinent to assess long-term effects on lipids. At
543 baseline, Week 26, and Week 52, mean LDL/HDL ratios were 3.1, 3.2, and 3.0, respectively, for
544 AVANDIA 4 mg twice daily. The corresponding values for glyburide were 3.2, 3.1, and 2.9. The
545 differences in change from baseline between AVANDIA and glyburide at Week 52 were
546 statistically significant.

547 The pattern of LDL and HDL changes following therapy with AVANDIA in combination with
548 other hypoglycemic agents were generally similar to those seen with AVANDIA in
549 monotherapy.

550 The changes in triglycerides during therapy with AVANDIA were variable and were generally
551 not statistically different from placebo or glyburide controls.

552 **Table 7. Summary of Mean Lipid Changes in 26-Week, Placebo-Controlled and 52-Week,**
553 **Glyburide-Controlled Monotherapy Trials**

Parameter	Placebo-Controlled Trials Week 26			Glyburide-Controlled Trial Week 26 and Week 52			
	Placebo	AVANDIA		Glyburide Titration		AVANDIA 8 mg	
		4 mg Daily ^a	8 mg Daily ^a	Week 26	Week 52	Week 26	Week 52
Free fatty acids							
N	207	428	436	181	168	166	145
Baseline (mean)	18.1	17.5	17.9	26.4	26.4	26.9	26.6
% Change from baseline (mean)	+0.2%	-7.8%	-14.7%	-2.4%	-4.7%	-20.8%	-21.5%
LDL

554 ^a Once-daily and twice-daily dosing groups were combined.

555 **12.3 Pharmacokinetics**

556 Maximum plasma concentration (C_{max}) and the area under the curve (AUC) of rosiglitazone
557 increase in a dose-proportional manner over the therapeutic dose range (Table 8). The
558 elimination half-life is 3 to 4 hours and is independent of dose.

559 **Table 8. Mean (SD) Pharmacokinetic Parameters for Rosiglitazone following Single Oral**
 560 **Doses (N = 32)**

Parameter	1 mg Fasting	2 mg Fasting	8 mg Fasting	8 mg Fed
AUC _{0-inf} (ng.h/mL)	358 (112)	733 (184)	2,971 (730)	2,890 (795)
C _{max} (ng/mL)	76 (13)	156 (42)	598 (117)	432 (92)
T _{1/2} (h)	3.16 (0.72)	3.15 (0.39)	3.37 (0.63)	3.59 (0.70)
CL/F (L/h)	3.03 (0.87)	2.89 (0.71)	2.85 (0.69)	2.97 (0.81)

561 AUC = area under the curve; C_{max} = maximum concentration; T_{1/2} = terminal half-life;
 562 CL/F = Oral clearance.

563 **Absorption**

564 The absolute bioavailability of rosiglitazone is 99%. Peak plasma concentrations are observed
 565 about 1 hour after dosing. Administration of rosiglitazone with food resulted in no change in
 566 overall exposure (AUC), but there was an approximately 28% decrease in C_{max} and a delay in
 567 T_{max} (1.75 hours). These changes are not likely to be clinically significant; therefore, AVANDIA
 568 may be administered with or without food.

569 **Distribution**

570 The mean (CV%) oral volume of distribution (V_{ss}/F) of rosiglitazone is approximately 17.6
 571 (30%) liters, based on a population pharmacokinetic analysis. Rosiglitazone is approximately
 572 99.8% bound to plasma proteins, primarily albumin.

573 **Metabolism**

574 Rosiglitazone is extensively metabolized with no unchanged drug excreted in the urine. The
 575 major routes of metabolism were N-demethylation and hydroxylation, followed by conjugation
 576 with sulfate and glucuronic acid. All the circulating metabolites are considerably less potent than
 577 parent and, therefore, are not expected to contribute to the insulin-sensitizing activity of
 578 rosiglitazone.

579 In vitro data demonstrate that rosiglitazone is predominantly metabolized by Cytochrome P450
 580 (CYP) isoenzyme 2C8, with CYP2C9 contributing as a minor pathway.

581 **Excretion**

582 Following oral or intravenous administration of [¹⁴C]rosiglitazone maleate, approximately 64%
 583 and 23% of the dose was eliminated in the urine and in the feces, respectively. The plasma half-
 584 life of [¹⁴C]related material ranged from 103 to 158 hours.

585 Population Pharmacokinetics in Patients with Type 2 Diabetes

586 Population pharmacokinetic analyses from 3 large clinical trials including 642 men and
587 405 women with type 2 diabetes (aged 35 to 80 years) showed that the pharmacokinetics of
588 rosiglitazone are not influenced by age, race, smoking, or alcohol consumption. Both oral
589 clearance (CL/F) and oral steady-state volume of distribution (V_{ss}/F) were shown to increase
590 with increases in body weight. Over the weight range observed in these analyses (50 to 150 kg),
591 the range of predicted CL/F and V_{ss}/F values varied by <1.7-fold and <2.3-fold, respectively.
592 Additionally, rosiglitazone CL/F was shown to be influenced by both weight and gender, being
593 lower (about 15%) in female patients.

594 Special Populations

595 *Geriatric:* Results of the population pharmacokinetic analysis (n = 716 <65 years; n = 331
596 ≥65 years) showed that age does not significantly affect the pharmacokinetics of rosiglitazone.

597 *Gender:* Results of the population pharmacokinetics analysis showed that the mean oral
598 clearance of rosiglitazone in female patients (n = 405) was approximately 6% lower compared
599 with male patients of the same body weight (n = 642).

600 As monotherapy and in combination with metformin, AVANDIA improved glycemic control in
601 both males and females. In metformin combination trials, efficacy was demonstrated with no
602 gender differences in glycemic response.

603 In monotherapy trials, a greater therapeutic response was observed in females; however, in more
604 obese patients, gender differences were less evident. For a given BMI, females tend to have a
605 greater fat mass than males. Since the molecular target PPAR γ is expressed in adipose tissues,
606 this differentiating characteristic may account, at least in part, for the greater response to
607 AVANDIA in females. Since therapy should be individualized, no dose adjustments are
608 necessary based on gender alone.

609 *Hepatic Impairment:* Unbound oral clearance of rosiglitazone was significantly lower in
610 patients with moderate to severe liver disease (Child-Pugh Class B/C) compared with healthy
611 subjects. As a result, unbound C_{max} and AUC_{0-inf} were increased 2- and 3-fold, respectively.
612 Elimination half-life for rosiglitazone was about 2 hours longer in patients with liver disease,
613 compared with healthy subjects.

614 Therapy with AVANDIA should not be initiated if the patient exhibits clinical evidence of active
615 liver disease or increased serum transaminase levels (ALT >2.5X upper limit of normal) at
616 baseline [see *Warnings and Precautions (5.5)*].

617 *Pediatric:* Pharmacokinetic parameters of rosiglitazone in pediatric patients were established
618 using a population pharmacokinetic analysis with sparse data from 96 pediatric patients in a
619 single pediatric clinical trial including 33 males and 63 females with ages ranging from 10 to
620 17 years (weights ranging from 35 to 178.3 kg). Population mean CL/F and V/F of rosiglitazone
621 were 3.15 L/h and 13.5 L, respectively. These estimates of CL/F and V/F were consistent with

622 the typical parameter estimates from a prior adult population analysis.

623 *Renal Impairment:* There are no clinically relevant differences in the pharmacokinetics of
624 rosiglitazone in patients with mild to severe renal impairment or in hemodialysis-dependent
625 patients compared with subjects with normal renal function. No dosage adjustment is therefore
626 required in such patients receiving AVANDIA. Since metformin is contraindicated in patients
627 with renal impairment, coadministration of metformin with AVANDIA is contraindicated in
628 these patients.

629 *Race:* Results of a population pharmacokinetic analysis including subjects of Caucasian, black,
630 and other ethnic origins indicate that race has no influence on the pharmacokinetics of
631 rosiglitazone.

632 **12.4 Drug-Drug Interactions**

633 Drugs that Inhibit, Induce, or are Metabolized by Cytochrome P450

634 In vitro drug metabolism studies suggest that rosiglitazone does not inhibit any of the major
635 P450 enzymes at clinically relevant concentrations. In vitro data demonstrate that rosiglitazone is
636 predominantly metabolized by CYP2C8, and to a lesser extent, 2C9. AVANDIA (4 mg twice
637 daily) was shown to have no clinically relevant effect on the pharmacokinetics of nifedipine and
638 oral contraceptives (ethinyl estradiol and norethindrone), which are predominantly metabolized
639 by CYP3A4.

640 *Gemfibrozil:* Concomitant administration of gemfibrozil (600 mg twice daily), an inhibitor of
641 CYP2C8, and rosiglitazone (4 mg once daily) for 7 days increased rosiglitazone AUC by 127%,
642 compared with the administration of rosiglitazone (4 mg once daily) alone. Given the potential
643 for dose-related adverse events with rosiglitazone, a decrease in the dose of rosiglitazone may be
644 needed when gemfibrozil is introduced [*see Drug Interactions (7.1)*].

645 *Rifampin:* Rifampin administration (600 mg once a day), an inducer of CYP2C8, for 6 days is
646 reported to decrease rosiglitazone AUC by 66%, compared with the administration of
647 rosiglitazone (8 mg) alone [*see Drug Interactions (7.1)*].¹

648 Glyburide

649 AVANDIA (2 mg twice daily) taken concomitantly with glyburide (3.75 to 10 mg/day) for
650 7 days did not alter the mean steady-state 24-hour plasma glucose concentrations in diabetic
651 patients stabilized on glyburide therapy. Repeat doses of AVANDIA (8 mg once daily) for 8
652 days in healthy adult Caucasian subjects caused a decrease in glyburide AUC and C_{max} of
653 approximately 30%. In Japanese subjects, glyburide AUC and C_{max} slightly increased following
654 coadministration of AVANDIA.

655 Glimepiride

656 Single oral doses of glimepiride in 14 healthy adult subjects had no clinically significant effect
657 on the steady-state pharmacokinetics of AVANDIA. No clinically significant reductions in

658 glimepiride AUC and C_{max} were observed after repeat doses of AVANDIA (8 mg once daily) for
659 8 days in healthy adult subjects.

660 Metformin

661 Concurrent administration of AVANDIA (2 mg twice daily) and metformin (500 mg twice daily)
662 in healthy volunteers for 4 days had no effect on the steady-state pharmacokinetics of either
663 metformin or rosiglitazone.

664 Acarbose

665 Coadministration of acarbose (100 mg three times daily) for 7 days in healthy volunteers had no
666 clinically relevant effect on the pharmacokinetics of a single oral dose of AVANDIA.

667 Digoxin

668 Repeat oral dosing of AVANDIA (8 mg once daily) for 14 days did not alter the steady-state
669 pharmacokinetics of digoxin (0.375 mg once daily) in healthy volunteers.

670 Warfarin

671 Repeat dosing with AVANDIA had no clinically relevant effect on the steady-state
672 pharmacokinetics of warfarin enantiomers.

673 Ethanol

674 A single administration of a moderate amount of alcohol did not increase the risk of acute
675 hypoglycemia in patients with type 2 diabetes mellitus treated with AVANDIA.

676 Ranitidine

677 Pre-treatment with ranitidine (150 mg twice daily for 4 days) did not alter the pharmacokinetics
678 of either single oral or intravenous doses of rosiglitazone in healthy volunteers. These results
679 suggest that the absorption of oral rosiglitazone is not altered in conditions accompanied by
680 increases in gastrointestinal pH.

681 **13 NONCLINICAL TOXICOLOGY**

682 **13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility**

683 Carcinogenesis

684 A 2-year carcinogenicity study was conducted in Charles River CD-1 mice at doses of 0.4, 1.5,
685 and 6 mg/kg/day in the diet (highest dose equivalent to approximately 12 times human AUC at
686 the maximum recommended human daily dose). Sprague-Dawley rats were dosed for 2 years by
687 oral gavage at doses of 0.05, 0.3, and 2 mg/kg/day (highest dose equivalent to approximately 10
688 and 20 times human AUC at the maximum recommended human daily dose for male and female
689 rats, respectively).

690 Rosiglitazone was not carcinogenic in the mouse. There was an increase in incidence of adipose

691 hyperplasia in the mouse at doses ≥ 1.5 mg/kg/day (approximately 2 times human AUC at the
692 maximum recommended human daily dose). In rats, there was a significant increase in the
693 incidence of benign adipose tissue tumors (lipomas) at doses ≥ 0.3 mg/kg/day (approximately
694 2 times human AUC at the maximum recommended human daily dose). These proliferative
695 changes in both species are considered due to the persistent pharmacological overstimulation of
696 adipose tissue.

697 Mutagenesis

698 Rosiglitazone was not mutagenic or clastogenic in the in vitro bacterial assays for gene mutation,
699 the in vitro chromosome aberration test in human lymphocytes, the in vivo mouse micronucleus
700 test, and the in vivo/in vitro rat UDS assay. There was a small (about 2-fold) increase in mutation
701 in the in vitro mouse lymphoma assay in the presence of metabolic activation.

702 Impairment of Fertility

703 Rosiglitazone had no effects on mating or fertility of male rats given up to 40 mg/kg/day
704 (approximately 116 times human AUC at the maximum recommended human daily dose).
705 Rosiglitazone altered estrous cyclicity (2 mg/kg/day) and reduced fertility (40 mg/kg/day) of
706 female rats in association with lower plasma levels of progesterone and estradiol (approximately
707 20 and 200 times human AUC at the maximum recommended human daily dose, respectively).
708 No such effects were noted at 0.2 mg/kg/day (approximately 3 times human AUC at the
709 maximum recommended human daily dose). In juvenile rats dosed from 27 days of age through
710 to sexual maturity (at up to 40 mg/kg/day), there was no effect on male reproductive
711 performance, or on estrous cyclicity, mating performance, or pregnancy incidence in females
712 (approximately 68 times human AUC at the maximum recommended human daily dose). In
713 monkeys, rosiglitazone (0.6 and 4.6 mg/kg/day; approximately 3 and 15 times human AUC at
714 the maximum recommended human daily dose, respectively) diminished the follicular phase rise
715 in serum estradiol with consequential reduction in the luteinizing hormone surge, lower luteal
716 phase progesterone levels, and amenorrhea. The mechanism for these effects appears to be direct
717 inhibition of ovarian steroidogenesis.

718 **13.2 Animal Toxicology**

719 Heart weights were increased in mice (3 mg/kg/day), rats (5 mg/kg/day), and dogs (2 mg/kg/day)
720 with rosiglitazone treatments (approximately 5, 22, and 2 times human AUC at the maximum
721 recommended human daily dose, respectively). Effects in juvenile rats were consistent with those
722 seen in adults. Morphometric measurement indicated that there was hypertrophy in cardiac
723 ventricular tissues, which may be due to increased heart work as a result of plasma volume
724 expansion.

725 **14 CLINICAL STUDIES**

726 **14.1 Monotherapy**

727 In clinical trials, treatment with AVANDIA resulted in an improvement in glycemic control, as
728 measured by FPG and HbA1c, with a concurrent reduction in insulin and C-peptide. Postprandial
729 glucose and insulin were also reduced. This is consistent with the mechanism of action of
730 AVANDIA as an insulin sensitizer.

731 The maximum recommended daily dose is 8 mg. Dose-ranging trials suggested that no additional
732 benefit was obtained with a total daily dose of 12 mg.

733 Short-term Clinical Trials

734 A total of 2,315 patients with type 2 diabetes, previously treated with diet alone or antidiabetic
735 medication(s), were treated with AVANDIA as monotherapy in 6 double-blind trials, which
736 included two 26-week, placebo-controlled trials; one 52-week, glyburide-controlled trial; and 3
737 placebo-controlled, dose-ranging trials of 8 to 12 weeks' duration. Previous antidiabetic
738 medication(s) were withdrawn and patients entered a 2- to 4-week placebo run-in period prior to
739 randomization.

740 Two 26-week, double-blind, placebo-controlled trials, in patients with type 2 diabetes
741 (n = 1,401) with inadequate glycemic control [mean baseline FPG approximately 228 mg/dL
742 (101 to 425 mg/dL) and mean baseline HbA1c 8.9% (5.2% to 16.2%)], were conducted.
743 Treatment with AVANDIA produced statistically significant improvements in FPG and HbA1c
744 compared with baseline and relative to placebo. Data from one of these trials are summarized in
745 Table 9.

746

Table 9. Glycemic Parameters in a 26-Week, Placebo-Controlled Trial

Parameter	Placebo	AVANDIA		AVANDIA	
	N = 173	4 mg Once Daily N = 180	2 mg Twice Daily N = 186	8 mg Once Daily N = 181	4 mg Twice Daily N = 187
FPG (mg/dL)					
Baseline (mean)	225	229	225	228	228
Change from baseline (mean)	8	-25	-35	-42	-55
Difference from placebo (adjusted mean)	–	-31 ^a	-43 ^a	-49 ^a	-62 ^a
% of patients with ≥30 mg/dL decrease from baseline	19%	45%	54%	58%	70%
HbA1c (%)					
Baseline (mean)	8.9	8.9	8.9	8.9	9.0
Change from baseline (mean)	0.8	0.0	-0.1	-0.3	-0.7
Difference from placebo (adjusted mean)	–	-0.8 ^a	-0.9 ^a	-1.1 ^a	-1.5 ^a
% of patients with ≥0.7% decrease from baseline	9%	28%	29%	39%	54%

747 ^a *P* <0.0001 compared with placebo.

748 When administered at the same total daily dose, AVANDIA was generally more effective in
749 reducing FPG and HbA1c when administered in divided doses twice daily compared with once-
750 daily doses. However, for HbA1c, the difference between the 4-mg once-daily and 2-mg twice-
751 daily doses was not statistically significant.

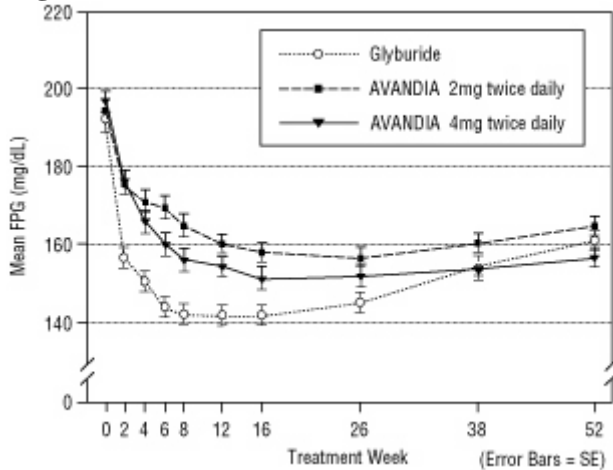

752 Long-term Clinical Trials

753 Long-term maintenance of effect was evaluated in a 52-week, double-blind, glyburide-controlled
754 trial in patients with type 2 diabetes. Patients were randomized to treatment with AVANDIA
755 2 mg twice daily (N = 195) or AVANDIA 4 mg twice daily (N = 189) or glyburide (N = 202) for
756 52 weeks. Patients receiving glyburide were given an initial dosage of either 2.5 mg/day or
757 5.0 mg/day. The dosage was then titrated in 2.5-mg/day increments over the next 12 weeks, to a
758 maximum dosage of 15.0 mg/day in order to optimize glycemic control. Thereafter, the
759 glyburide dose was kept constant.

760 The median titrated dose of glyburide was 7.5 mg. All treatments resulted in a statistically
761 significant improvement in glycemic control from baseline (Figure 3 and Figure 4). At the end of
762 Week 52, the reduction from baseline in FPG and HbA1c was -40.8 mg/dL and -0.53% with
763 AVANDIA 4 mg twice daily; -25.4 mg/dL and -0.27% with AVANDIA 2 mg twice daily; and -
764 30.0 mg/dL and -0.72% with glyburide. For HbA1c, the difference between AVANDIA 4 mg

765 twice daily and glyburide was not statistically significant at Week 52. The initial fall in FPG with
 766 glyburide was greater than with AVANDIA; however, this effect was less durable over time. The
 767 improvement in glycemic control seen with AVANDIA 4 mg twice daily at Week 26 was
 768 maintained through Week 52 of the trial.

769 **Figure 3. Mean FPG over Time in a 52-Week, Glyburide-Controlled Trial**

770

771 **Figure 4. Mean HbA1c over Time in a 52-Week, Glyburide-Controlled Trial**

772

773 Hypoglycemia was reported in 12.1% of glyburide-treated patients versus 0.5% (2 mg twice
 774 daily) and 1.6% (4 mg twice daily) of patients treated with AVANDIA. The improvements in
 775 glycemic control were associated with a mean weight gain of 1.75 kg and 2.95 kg for patients
 776 treated with 2 mg and 4 mg twice daily of AVANDIA, respectively, versus 1.9 kg in glyburide-
 777 treated patients. In patients treated with AVANDIA, C-peptide, insulin, pro-insulin, and pro-
 778 insulin split products were significantly reduced in a dose-ordered fashion, compared with an
 779 increase in the glyburide-treated patients.

780 A Diabetes Outcome Progression Trial (ADOPT) was a multicenter, double-blind, controlled
 781 trial (N = 4,351) conducted over 4 to 6 years to compare the safety and efficacy of AVANDIA,

782 metformin, and glyburide monotherapy in patients recently diagnosed with type 2 diabetes
783 mellitus (≤ 3 years) inadequately controlled with diet and exercise. The mean age of patients in
784 this trial was 57 years and the majority of patients (83%) had no known history of cardiovascular
785 disease. The mean baseline FPG and HbA1c were 152 mg/dL and 7.4%, respectively. Patients
786 were randomized to receive either AVANDIA 4 mg once daily, glyburide 2.5 mg once daily, or
787 metformin 500 mg once daily, and doses were titrated to optimal glycemic control up to a
788 maximum of 4 mg twice daily for AVANDIA, 7.5 mg twice daily for glyburide, and 1,000 mg
789 twice daily for metformin. The primary efficacy outcome was time to consecutive FPG
790 >180 mg/dL after at least 6 weeks of treatment at the maximum tolerated dose of study
791 medication or time to inadequate glycemic control, as determined by an independent
792 adjudication committee.

793 The cumulative incidence of the primary efficacy outcome at 5 years was 15% with AVANDIA,
794 21% with metformin, and 34% with glyburide (HR 0.68 [95% CI: 0.55, 0.85] versus metformin,
795 HR 0.37 [95% CI: 0.30, 0.45] versus glyburide).

796 Cardiovascular and adverse event data (including effects on body weight and bone fracture) from
797 ADOPT for AVANDIA, metformin, and glyburide are described in *Warnings and Precautions*
798 (5.2, 5.4, and 5.7) and *Adverse Reactions* (6.1), respectively. As with all medications, efficacy
799 results must be considered together with safety information to assess the potential benefit and
800 risk for an individual patient.

801 **14.2 Combination with Metformin or Sulfonylurea**

802 The addition of AVANDIA to either metformin or sulfonylurea resulted in significant reductions
803 in hyperglycemia compared with either of these agents alone. These results are consistent with
804 an additive effect on glycemic control when AVANDIA is used as combination therapy.

805 Combination with Metformin

806 A total of 670 patients with type 2 diabetes participated in two 26-week, randomized, double-
807 blind, placebo/active-controlled trials designed to assess the efficacy of AVANDIA in
808 combination with metformin. AVANDIA, administered in either once-daily or twice-daily
809 dosing regimens, was added to the therapy of patients who were inadequately controlled on a
810 maximum dose (2.5 grams/day) of metformin.

811 In one trial, patients inadequately controlled on 2.5 grams/day of metformin (mean baseline FPG
812 216 mg/dL and mean baseline HbA1c 8.8%) were randomized to receive 4 mg of AVANDIA
813 once daily, 8 mg of AVANDIA once daily, or placebo in addition to metformin. A statistically
814 significant improvement in FPG and HbA1c was observed in patients treated with the
815 combinations of metformin and 4 mg of AVANDIA once daily and 8 mg of AVANDIA once
816 daily, versus patients continued on metformin alone (Table 10).

817 **Table 10. Glycemic Parameters in a 26-Week Combination Trial of AVANDIA plus**
 818 **Metformin**

Parameter	Metformin N = 113	AVANDIA 4 mg Once Daily + Metformin N = 116	AVANDIA 8 mg Once Daily + Metformin N = 110
FPG (mg/dL)			
Baseline (mean)	214	215	220
Change from baseline (mean)	6	-33	-48
Difference from metformin alone (adjusted mean)	-	-40 ^a	-53 ^a
% of patients with ≥ 30 mg/dL decrease from baseline	20%	45%	61%
HbA1c (%)			
Baseline (mean)	8.6	8.9	8.9
Change from baseline (mean)	0.5	-0.6	-0.8
Difference from metformin alone (adjusted mean)	-	-1.0 ^a	-1.2 ^a
% of patients with $\geq 0.7\%$ decrease from baseline	11%	45%	52%

819 ^a $P < 0.0001$ compared with metformin.

820 In a second 26-week trial, patients with type 2 diabetes inadequately controlled on 2.5 grams/day
 821 of metformin who were randomized to receive the combination of AVANDIA 4 mg twice daily
 822 and metformin (N = 105) showed a statistically significant improvement in glycemic control
 823 with a mean treatment effect for FPG of -56 mg/dL and a mean treatment effect for HbA1c of -
 824 0.8% over metformin alone. The combination of metformin and AVANDIA resulted in lower
 825 levels of FPG and HbA1c than either agent alone.

826 Patients who were inadequately controlled on a maximum dose (2.5 grams/day) of metformin
 827 and who were switched to monotherapy with AVANDIA demonstrated loss of glycemic control,
 828 as evidenced by increases in FPG and HbA1c. In this group, increases in LDL and VLDL were
 829 also seen.

830 Combination with a Sulfonylurea

831 A total of 3,457 patients with type 2 diabetes participated in ten 24- to 26-week randomized,
 832 double-blind, placebo/active-controlled trials and one 2-year double-blind, active-controlled trial
 833 in elderly patients designed to assess the efficacy and safety of AVANDIA in combination with a
 834 sulfonylurea. AVANDIA 2 mg, 4 mg, or 8 mg daily was administered, either once daily (3 trials)
 835 or in divided doses twice daily (7 trials), to patients inadequately controlled on a submaximal or

836 maximal dose of sulfonylurea.

837 In these trials, the combination of AVANDIA 4 mg or 8 mg daily (administered as single- or
838 twice-daily divided doses) and a sulfonylurea significantly reduced FPG and HbA1c compared
839 with placebo plus sulfonylurea or further up-titration of the sulfonylurea. Table 11 shows pooled
840 data for 8 trials in which AVANDIA added to sulfonylurea was compared with placebo plus
841 sulfonylurea.

842 **Table 11. Glycemic Parameters in 24- to 26-Week Combination Trials of AVANDIA plus**
843 **Sulfonylurea**

Twice-Daily Divided Dosing (5 Trials)	Sulfonylurea N = 397	AVANDIA 2 mg Twice Daily + Sulfonylurea N = 497	Sulfonylurea N = 248	AVANDIA 4 mg Twice Daily + Sulfonylurea N = 346
FPG (mg/dL)				
Baseline (mean)	204	198	188	187
Change from baseline (mean)	11	-29	8	-43
Difference from sulfonylurea alone (adjusted mean)	–	-42 ^a	–	-53 ^a
% of patients with ≥30 mg/dL decrease from baseline	17%	49%	15%	61%
HbA1c (%)				
Baseline (mean)	9.4	9.5	9.3	9.6
Change from baseline (mean)	0.2	-1.0	0.0	-1.6
Difference from sulfonylurea alone (adjusted mean)	–	-1.1 ^a	–	-1.4 ^a
% of patients with ≥0.7% decrease from baseline	21%	60%	23%	75%
Once-Daily Dosing (3 Trials)	Sulfonylurea N = 172	AVANDIA 4 mg Once Daily + Sulfonylurea N = 172	Sulfonylurea N = 173	AVANDIA 8 mg Once Daily + Sulfonylurea N = 176
FPG (mg/dL)				
Baseline (mean)	198	206	188	192
Change from baseline (mean)	17	-25	17	-43
Difference from sulfonylurea alone (adjusted mean)	–	-47 ^a	–	-66 ^a
% of patients with ≥30 mg/dL decrease from baseline	17%	48%	19%	55%
HbA1c (%)				
Baseline (mean)	8.6	8.8	8.9	8.9
Change from baseline (mean)	0.4	-0.5	0.1	-1.2
Difference from sulfonylurea alone (adjusted mean)	–	-0.9 ^a	–	-1.4 ^a
% of patients with ≥0.7% decrease from baseline	11%	36%	20%	68%

844 ^a *P* <0.0001 compared with sulfonylurea alone.

845 One of the 24- to 26-week trials included patients who were inadequately controlled on maximal
846 doses of glyburide and switched to 4 mg of AVANDIA daily as monotherapy; in this group, loss
847 of glycemic control was demonstrated, as evidenced by increases in FPG and HbA1c.

848 In a 2-year, double-blind trial, elderly patients (aged 59 to 89 years) on half-maximal
849 sulfonylurea (glipizide 10 mg twice daily) were randomized to the addition of AVANDIA
850 (n = 115, 4 mg once daily to 8 mg as needed) or to continued up-titration of glipizide (n = 110),
851 to a maximum of 20 mg twice daily. Mean baseline FPG and HbA1c were 157 mg/dL and
852 7.72%, respectively, for the arm receiving AVANDIA plus glipizide and 159 mg/dL and 7.65%,
853 respectively, for the glipizide up-titration arm. Loss of glycemic control (FPG \geq 180 mg/dL)
854 occurred in a significantly lower proportion of patients (2%) on AVANDIA plus glipizide
855 compared with patients in the glipizide up-titration arm (28.7%). About 78% of the patients on
856 combination therapy completed the 2 years of therapy while only 51% completed on glipizide
857 monotherapy. The effect of combination therapy on FPG and HbA1c was durable over the 2-year
858 trial period, with patients achieving a mean of 132 mg/dL for FPG and a mean of 6.98% for
859 HbA1c compared with no change on the glipizide arm.

860 **14.3 Combination with Sulfonylurea plus Metformin**

861 In two 24- to 26-week, double-blind, placebo-controlled trials designed to assess the efficacy and
862 safety of AVANDIA in combination with sulfonylurea plus metformin, AVANDIA 4 mg or
863 8 mg daily, was administered in divided doses twice daily, to patients inadequately controlled on
864 submaximal (10 mg) and maximal (20 mg) doses of glyburide and maximal dose of metformin
865 (2 g/day). A statistically significant improvement in FPG and HbA1c was observed in patients
866 treated with the combinations of sulfonylurea plus metformin and 4 mg of AVANDIA and 8 mg
867 of AVANDIA versus patients continued on sulfonylurea plus metformin, as shown in Table 12.

868 **Table 12. Glycemic Parameters in a 26-Week Combination Trial of AVANDIA plus**
 869 **Sulfonylurea and Metformin**

Parameter	Sulfonylurea + Metformin N = 273	AVANDIA 2 mg Twice Daily + Sulfonylurea + Metformin N = 276	AVANDIA 4 mg Twice Daily + Sulfonylurea + Metformin N = 277
FPG (mg/dL)			
Baseline (mean)	189	190	192
Change from baseline (mean)	14	-19	-40
Difference from sulfonylurea plus metformin (adjusted mean)	–	-30 ^a	-52 ^a
% of patients with ≥30 mg/dL decrease from baseline	16%	46%	62%
HbA1c (%)			
Baseline (mean)	8.7	8.6	8.7
Change from baseline (mean)	0.2	-0.4	-0.9
Difference from sulfonylurea plus metformin (adjusted mean)	–	-0.6 ^a	-1.1 ^a
% of patients with ≥0.7% decrease from baseline	16%	39%	63%

870 ^a P <0.0001 compared with placebo.

 873 rosiglitazone in healthy subjects. *Clin Pharmacol Ther.* 2004;75:157-162.

874 **16 HOW SUPPLIED/STORAGE AND HANDLING**

875 Each pentagonal film-coated TILTAB tablet contains rosiglitazone as the maleate as follows: 2
 876 mg–pink, debossed with GSK on one side and 2 on the other; 4 mg–orange, debossed with GSK
 877 on one side and 4 on the other.

878 2 mg bottles of 60: NDC 0173-0861-18

879 4 mg bottles of 30: NDC 0173-0863-13

880 Store at 25°C (77°F); excursions 15° to 30°C (59° to 86°F). Dispense in a tight, light-resistant
 881 container.

882 **17 PATIENT COUNSELING INFORMATION**

883 Advise the patient to read the FDA-approved patient labeling (Medication Guide).

884 There are multiple medications available to treat type 2 diabetes. The benefits and risks of each
885 available diabetes medication should be taken into account when choosing a particular diabetes
886 medication for a given patient.

887 Patients should be informed of the following:

- 888 • AVANDIA is not recommended for patients with symptomatic heart failure.
- 889 • A meta-analysis of mostly short-term trials suggested an increased risk for myocardial
890 infarction with AVANDIA compared with placebo. Data from long-term clinical trials of
891 AVANDIA versus other antidiabetes agents (metformin or sulfonylureas), including a
892 cardiovascular outcome trial (RECORD), observed no difference in overall mortality or in
893 major adverse cardiovascular events (MACE) and its components.
- 894 • AVANDIA is not recommended for patients who are taking insulin.
- 895 • Management of type 2 diabetes should include diet control. Caloric restriction, weight loss,
896 and exercise are essential for the proper treatment of the diabetic patient because they help
897 improve insulin sensitivity. This is important not only in the primary treatment of type 2
898 diabetes, but in maintaining the efficacy of drug therapy.
- 899 • It is important to adhere to dietary instructions and to regularly have blood glucose and
900 glycosylated hemoglobin tested. It can take 2 weeks to see a reduction in blood glucose and 2
901 to 3 months to see the full effect of AVANDIA.
- 902 • Blood will be drawn to check their liver function prior to the start of therapy and periodically
903 thereafter per the clinical judgment of the healthcare professional. Patients with unexplained
904 symptoms of nausea, vomiting, abdominal pain, fatigue, anorexia, or dark urine should
905 immediately report these symptoms to their physician.
- 906 • Patients who experience an unusually rapid increase in weight or edema or who develop
907 shortness of breath or other symptoms of heart failure while on AVANDIA should
908 immediately report these symptoms to their physician.
- 909 • AVANDIA can be taken with or without meals.
- 910 • When using AVANDIA in combination with other hypoglycemic agents, the risk of
911 hypoglycemia, its symptoms and treatment, and conditions that predispose to its development
912 should be explained to patients and their family members.
- 913 • Therapy with AVANDIA, like other thiazolidinediones, may result in ovulation in some
914 premenopausal anovulatory women. As a result, these patients may be at an increased risk for
915 pregnancy while taking AVANDIA. Thus, adequate contraception in premenopausal women
916 should be recommended. This possible effect has not been specifically investigated in
917 clinical trials so the frequency of this occurrence is not known.

MEDICATION GUIDE
AVANDIA® (ah-VAN-dee-a)
(rosiglitazone maleate) tablets

Read this Medication Guide carefully before you start taking AVANDIA and each time you get a refill. There may be new information. This information does not take the place of talking with your doctor about your medical condition or your treatment. If you have any questions about AVANDIA, ask your doctor or pharmacist.

What is the most important information I should know about AVANDIA?

AVANDIA may cause serious side effects, including:

New or worse heart failure

- The risk of heart failure may be higher in people who take AVANDIA with insulin. Most people who take insulin should not also take AVANDIA.
- AVANDIA can cause your body to keep extra fluid (fluid retention), which leads to swelling (edema) and weight gain. Extra body fluid can make some heart problems worse or lead to heart failure. Heart failure means your heart does not pump blood well enough.
- If you have severe heart failure, you cannot start AVANDIA.
- If you have heart failure with symptoms (such as shortness of breath or swelling), even if these symptoms are not severe, AVANDIA may not be right for you.

Call your doctor right away if you have any of the following:

- swelling or fluid retention, especially in the ankles or legs
- shortness of breath or trouble breathing, especially when you lie down
- an unusually fast increase in weight
- unusual tiredness

AVANDIA can have other serious side effects. Be sure to read the section below "What are possible side effects of AVANDIA?"

What is AVANDIA?

AVANDIA is a prescription medicine used with diet and exercise to treat adults with type 2 ("adult-onset" or "non-insulin dependent") diabetes mellitus ("high blood sugar").

956 AVANDIA helps to control high blood sugar. AVANDIA may be used alone or with
957 other diabetes medicines. AVANDIA can help your body respond better to insulin
958 made in your body. AVANDIA does not cause your body to make more insulin.

959 AVANDIA is not for people with type 1 diabetes mellitus or to treat a condition
960 called diabetic ketoacidosis.

961 It is not known if AVANDIA is safe and effective in children younger than 18 years
962 old.

963 **Who should not take AVANDIA?**

964 Many people with heart failure should not start taking AVANDIA. See “What should
965 I tell my doctor before taking AVANDIA?”

966 **Do not** take AVANDIA if you are allergic to rosiglitazone or any of the ingredients in
967 AVANDIA. See the end of this leaflet for a complete list of ingredients in AVANDIA.

968 Symptoms of a severe allergic reaction with AVANDIA may include:

- 969 • swelling of your face, lips, tongue, or throat
- 970 • problems with breathing or swallowing
- 971 • skin rash or itching
- 972 • raised red areas on your skin (hives)
- 973 • blisters on your skin or in your mouth, nose, or eyes
- 974 • peeling of your skin
- 975 • fainting or feeling dizzy
- 976 • very rapid heartbeat

977 **What should I tell my doctor before taking AVANDIA?**

978 Before starting AVANDIA, ask your doctor about what the choices are for diabetes
979 medicines, and what the expected benefits and possible risks are for you in
980 particular.

981 Before taking AVANDIA, tell your doctor about all of your medical conditions,
982 including if you:

- 983 • **have heart problems or heart failure.**
- 984 • **have type 1 (“juvenile”) diabetes or had diabetic ketoacidosis.** These
985 conditions should be treated with insulin.
- 986 • **have a type of diabetic eye disease called macular edema** (swelling of the
987 back of the eye).

- 988 • **have liver problems.** Your doctor should do blood tests to check your liver
989 before you start taking AVANDIA and during treatment as needed.
- 990 • **had liver problems while taking REZULIN™ (troglitazone), another**
991 **medicine for diabetes.**
- 992 • **are pregnant or plan to become pregnant.** It is not known if AVANDIA can
993 harm your unborn baby. You and your doctor should talk about the best way to
994 control your diabetes during pregnancy. If you are a premenopausal woman
995 (before the “change of life”) who does not have regular monthly periods,
996 AVANDIA may increase your chances of becoming pregnant. Talk to your doctor
997 about birth control choices while taking AVANDIA. Tell your doctor right away if
998 you become pregnant while taking AVANDIA.
- 999 • **are breastfeeding or planning to breastfeed.** It is not known if AVANDIA
1000 passes into breast milk. You and your doctor should decide if you will take
1001 AVANDIA or breastfeed. You should not do both.

1002 Tell your doctor about all of the medicines you take including prescription and over-
1003 the-counter medicines, vitamins, or herbal supplements. AVANDIA and certain
1004 other medicines can affect each other and may lead to serious side effects including
1005 high or low blood sugar, or heart problems. Especially tell your doctor if you take:

- 1006 • **insulin.**
- 1007 • **any medicines for high blood pressure, high cholesterol, or heart failure,**
1008 **or for prevention of heart disease or stroke.**

1009 Know the medicines you take. Keep a list of your medicines and show it to your
1010 doctor and pharmacist before you start a new medicine. They will tell you if it is
1011 alright to take AVANDIA with other medicines.

1012 **How should I take AVANDIA?**

- 1013 • Take AVANDIA exactly as prescribed. Your doctor will tell you how many tablets
1014 to take and how often. The usual daily starting dose is 4 mg a day taken one
1015 time each day or 2 mg taken two times each day. Your doctor may need to
1016 adjust your dose until your blood sugar is better controlled.
- 1017 • AVANDIA may be prescribed alone or with other diabetes medicines. This will
1018 depend on how well your blood sugar is controlled.
- 1019 • Take AVANDIA with or without food.
- 1020 • It can take 2 weeks for AVANDIA to start lowering blood sugar. It may take 2 to
1021 3 months to see the full effect on your blood sugar level.
- 1022 • If you miss a dose of AVANDIA, take it as soon as you remember, unless it is

1023 time to take your next dose. Take your next dose at the usual time. Do not take
1024 double doses to make up for a missed dose.

1025 • If you take too much AVANDIA, call your doctor or poison control center right
1026 away.

1027 • Test your blood sugar regularly as your doctor tells you.

1028 • Diet and exercise can help your body use its blood sugar better. It is important
1029 to stay on your recommended diet, lose extra weight, and get regular exercise
1030 while taking AVANDIA.

1031 • Your doctor should do blood tests to check your liver before you start AVANDIA
1032 and during treatment as needed. Your doctor should also do regular blood sugar
1033 tests (for example, "A1C") to monitor your response to AVANDIA.

1034 **What are possible side effects of AVANDIA?**

1035 **AVANDIA may cause serious side effects including:**

1036 • **New or worse heart failure.** See "What is the most important information I
1037 should know about AVANDIA?"

1038 • **Heart attack.** AVANDIA may increase the risk of a heart attack. Talk to your
1039 doctor about what this means to you.

1040 **Symptoms of a heart attack can include the following:**

1041 • chest discomfort in the center of your chest that lasts for more than a few
1042 minutes, or that goes away or comes back

1043 • chest discomfort that feels like uncomfortable pressure, squeezing, fullness, or
1044 pain

1045 • pain or discomfort in your arms, back, neck, jaw, or stomach

1046 • shortness of breath with or without chest discomfort

1047 • breaking out in a cold sweat

1048 • nausea or vomiting

1049 • feeling lightheaded

1050 **Call your doctor or go to the nearest hospital emergency room right** 1051 **away if you think you are having a heart attack.**

1052 • **Swelling (edema).** AVANDIA can cause swelling due to fluid retention. See
1053 "What is the most important information I should know about AVANDIA?"

1054 • **Weight gain.** AVANDIA can cause weight gain that may be due to fluid

1055 retention or extra body fat. Weight gain can be a serious problem for people
1056 with certain conditions including heart problems. See “What is the most
1057 important information I should know about AVANDIA?”

1058 • **Liver problems.** It is important for your liver to be working normally when you
1059 take AVANDIA. Your doctor should do blood tests to check your liver before you
1060 start taking AVANDIA and during treatment as needed. Call your doctor right
1061 away if you have unexplained symptoms such as:

- 1062 • nausea or vomiting
- 1063 • stomach pain
- 1064 • unusual or unexplained tiredness
- 1065 • loss of appetite
- 1066 • dark urine
- 1067 • yellowing of your skin or the whites of your eyes.

1068 • **Macular edema** (a diabetic eye disease with swelling in the back of the eye).
1069 Tell your doctor right away if you have any changes in your vision. Your doctor
1070 should check your eyes regularly. Very rarely, some people have had vision
1071 changes due to swelling in the back of the eye while taking AVANDIA.

1072 • **Fractures (broken bones)**, usually in the hand, upper arm, or foot. Talk to
1073 your doctor for advice on how to keep your bones healthy.

1074 • **Low red blood cell count (anemia).**

1075 • **Low blood sugar (hypoglycemia).** Lightheadedness, dizziness, shakiness, or
1076 hunger may mean that your blood sugar is too low. This can happen if you skip
1077 meals, if you use another medicine that lowers blood sugar, or if you have
1078 certain medical problems. Call your doctor if low blood sugar levels are a
1079 problem for you.

1080 • **Ovulation** (release of egg from an ovary in a woman) leading to pregnancy.
1081 Ovulation may happen in premenopausal women who do not have regular
1082 monthly periods. This can increase the chance of pregnancy. See “What should I
1083 tell my doctor before taking AVANDIA?”

1084 The most common side effects of AVANDIA reported in clinical trials included cold-
1085 like symptoms and headache.

1086 Call your doctor for medical advice about side effects. You may report side effects
1087 to FDA at 1-800-FDA-1088.

1088 **How should I store AVANDIA?**

- 1089 • Store AVANDIA at room temperature, 59°F to 86°F (15°C to 30°C). Keep
1090 AVANDIA in the container it comes in.
- 1091 • Safely, throw away AVANDIA that is out of date or no longer needed.
- 1092 • Keep AVANDIA and all medicines out of the reach of children.

1093 **General information about AVANDIA**

1094 Medicines are sometimes prescribed for purposes other than those listed in a
1095 Medication Guide. Do not use AVANDIA for a condition for which it was not
1096 prescribed. Do not give AVANDIA to other people, even if they have the same
1097 symptoms you have. It may harm them.

1098 This Medication Guide summarizes important information about AVANDIA. If you
1099 would like more information, talk with your doctor. You can ask your doctor or
1100 pharmacist for information about AVANDIA that is written for healthcare
1101 professionals. You can also find out more about AVANDIA by calling 1-888-825-
1102 5249.

1103 **What are the ingredients in AVANDIA?**

1104 Active Ingredient: rosiglitazone maleate.

1105 Inactive Ingredients: hypromellose 2910, lactose monohydrate, magnesium
1106 stearate, microcrystalline cellulose, polyethylene glycol 3000, sodium starch
1107 glycolate, titanium dioxide, triacetin, and 1 or more of the following: synthetic red
1108 and yellow iron oxides and talc.

1109 Always check to make sure that the medicine you are taking is the correct one.
1110 AVANDIA tablets are triangles with rounded corners and look like this:

1111 2 mg – pink with "GSK" on one side and "2" on the other.

1112 4 mg – orange with "GSK" on one side and "4" on the other.

1113 AVANDIA is a registered trademark of the GSK group of companies.

1114 REZULIN is a trademark of its respective owner and is not a trademark of the GSK
1115 group of companies. The maker of this brand is not affiliated with and does not
1116 endorse the GSK group of companies or its products.

1117 **This Medication Guide has been approved by the U.S. Food and Drug**
1118 **Administration.**
