

2.2 Recommended Dosage

COMPLERA is a three-drug fixed dose combination product containing 200 mg of emtricitabine (FTC), 25 mg of rilpivirine (RPV), and 300 mg of tenofovir disoproxil fumarate (TDF). The recommended dosage of COMPLERA in adult and pediatric patients weighing at least 35 kg is one tablet taken orally once daily with food [see *Use in Specific Populations (8.4) and Clinical Pharmacology (12.3)*].

2.3 Recommended Dosage During Pregnancy

For pregnant patients who are already on COMPLERA prior to pregnancy and are virologically suppressed (HIV-1 RNA less than 50 copies per mL), one tablet of COMPLERA taken once daily may be continued. Lower exposures of rilpivirine, a component of COMPLERA, were observed during pregnancy, therefore viral load should be monitored closely [see *Use in Specific Populations (8.1) and Clinical Pharmacology (12.3)*].

2.4 Not Recommended in Patients with Moderate or Severe Renal Impairment

COMPLERA is not recommended in patients with moderate or severe renal impairment (estimated creatinine clearance below 50 mL per minute) [see *Warnings and Precautions (5.5) and Use in Specific Populations (8.6)*].

2.5 Recommended Dosage with Rifabutin Coadministration

If COMPLERA is coadministered with rifabutin, take an additional 25 mg tablet of rilpivirine (Edurant[®]) with COMPLERA once daily with a meal for the duration of the rifabutin coadministration [see *Drug Interactions (7.6) and Clinical Pharmacology (12.3)*].

3 DOSAGE FORMS AND STRENGTHS

Each COMPLERA tablet contains 200 mg of emtricitabine (FTC), 27.5 mg of rilpivirine hydrochloride (equivalent to 25 mg of rilpivirine [RPV]), and 300 mg of tenofovir disoproxil fumarate (TDF, equivalent to 245 mg of tenofovir disoproxil).

The tablets are purplish pink, capsule shaped, film coated, debossed with “GSI” on one side, and plain faced on the other side.

4 CONTRAINDICATIONS

COMPLERA is contraindicated when coadministered with the following drugs; coadministration may result in loss of virologic response and possible resistance to COMPLERA or to the class of NNRTIs [see *Warnings and Precautions (5.7), Drug Interactions (7), and Clinical Pharmacology (12.3)*]:

- Anticonvulsants: carbamazepine, oxcarbazepine, phenobarbital, phenytoin
- Antimycobacterials: rifampin, rifapentine

In the RPV group, 43/588 (7.3%) of subjects with a normal 250 micrograms ACTH stimulation test at baseline developed an abnormal 250 micrograms ACTH stimulation test (peak cortisol level <18.1 micrograms/dL) during the trial compared to 18/561 (3.2%) in the EFV group. Of the subjects who developed an abnormal 250 micrograms ACTH stimulation test during the trial, 14 subjects in the RPV group and 9 subjects in the EFV group had an abnormal 250 micrograms ACTH stimulation test at Week 96. Overall, there were no serious adverse events, deaths, or treatment discontinuations that could clearly be attributed to adrenal insufficiency. The clinical significance of the higher abnormal rate of 250 micrograms ACTH stimulation tests in the RPV group is not known.

Serum Creatinine: In the pooled Phase 3 trials of C209 and C215 in subjects treated with RPV plus any of the allowed background regimens (N=686), there was a small increase in serum creatinine over 96 weeks of treatment with RPV. Most of this increase occurred within the first 4 weeks of treatment, with a mean change of 0.1 mg/dL (range –0.3 to 0.6 mg/dL) observed through Week 96. In subjects who entered the trial with mild or moderate renal impairment, the serum creatinine increase observed was similar to that seen in subjects with normal renal function. These changes are not considered to be clinically relevant, and no subject discontinued treatment due to increases in serum creatinine. Creatinine increases were comparable by background N(t)RTIs.

Serum Lipids: Changes from baseline in total cholesterol, LDL-cholesterol, and triglycerides are presented in Table 3.

Table 3 Lipid Values Reported in Adult Subjects Receiving RPV or EFV in Combination with FTC/TDF in Studies C209 and C215^a

	Pooled Data from the Week 96 Analysis of C209 and C215 Trials							
	RPV + FTC/TDF N=550				EFV + FTC/TDF N=546			
	N	Baseline	Week 96		N	Baseline	Week 96	
Mean		Mean (mg/dL)	Mean (mg/dL)	Mean Change ^b (mg/dL)		Mean (mg/dL)	Mean (mg/dL)	Mean Change ^b (mg/dL)
Total Cholesterol (fasted)	430	162	164	2	401	160	186	26
HDL-cholesterol (fasted)	429	42	45	4	399	40	50	11
LDL-cholesterol (fasted)	427	97	97	–1	397	96	110	14
Triglycerides (fasted)	430	123	109	–14	401	127	133	6

N=number of subjects per treatment group

a. Excludes subjects who received lipid lowering agents during the treatment period.

b. The change from baseline is the mean of within-patient changes from baseline for patients with both baseline and Week 96 values.

Adult Subjects Coinfected with Hepatitis B and/or Hepatitis C Virus: In adult subjects coinfecting with hepatitis B or C virus receiving RPV in studies C209 and C215, the incidence of hepatic enzyme elevation was higher than in subjects receiving RPV who were not coinfecting. The same increase was also observed in the EFV arm. The pharmacokinetic exposure of RPV in coinfecting subjects was comparable to that in subjects without coinfection.

Adverse Reactions from Clinical Trials Experience in Pediatric Subjects

Emtricitabine: In addition to the adverse reactions reported in adults, anemia and hyperpigmentation were observed in 7% and 32%, respectively, of pediatric subjects (3 months to less than 18 years of age) who received treatment with FTC in the larger of two open-label, uncontrolled pediatric trials (N=116). For additional information, please consult the EMTRIVA prescribing information.

Rilpivirine: The safety assessment is based on the Week 48 analysis of the single-arm, open-label Phase 2 trial, TMC278-C213, in which 36 antiretroviral treatment-naïve HIV-1-infected subjects 12 to less than 18 years of age and weighing at least 32 kg received RPV (25 mg once daily) in combination with other antiretroviral agents. The median duration of exposure for subjects was 63.5 weeks. No subjects discontinued treatment due to adverse reactions. No new adverse reactions were identified compared to those seen in adults.

Adverse reactions were reported in 19 pediatric subjects (52.8%). Most adverse reactions were Grade 1 or 2. The most common adverse reactions reported in at least 2 subjects (regardless of severity) include headache (19.4%), depression (19.4%), somnolence (13.9%), nausea (11.1%), dizziness (8.3%), abdominal pain (8.3%), vomiting (5.6%), and rash (5.6%).

Observed laboratory abnormalities were comparable to those in adults. For additional information, please consult the Edurant prescribing information.

Adrenal Function

In trial TMC278-C213, at Week 48, the overall mean change from baseline in basal cortisol showed an increase of 1.59 (0.24, 2.93) micrograms/dL.

Six of 30 (20%) subjects with a normal 250 micrograms ACTH stimulation test at baseline developed an abnormal 250 micrograms ACTH stimulation test (peak cortisol level <18.1 micrograms/dL) during the trial. Three of these subjects had an abnormal 250 micrograms ACTH stimulation test at Week 48. Overall, there were no serious adverse events, deaths, or treatment discontinuations that could clearly be attributed to adrenal insufficiency. The clinical significance of the abnormal 250 micrograms ACTH stimulation tests is not known.

Tenofovir DF: In a pediatric clinical trial conducted in subjects 12 to less than 18 years of age, the adverse reactions observed in pediatric subjects who received treatment with TDF were consistent with those observed in clinical trials of TDF in adults [see *Warnings*

and Precautions (5.6)]. For additional information, including information on bone mineral density changes, please consult the VIREAD prescribing information.

6.2 Postmarketing Experience

The following adverse reactions have been identified during postmarketing experience in patients receiving RPV- or TDF-containing regimens. Because postmarketing reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

COMPLERA:

Metabolism and Nutrition Disorders

weight increased

Skin and Subcutaneous Tissue Disorders

severe skin and hypersensitivity reactions including DRESS (Drug Reaction with Eosinophilia and Systemic Symptoms)

Rilpivirine:

Renal and Urinary Disorders

nephrotic syndrome

Emtricitabine:

No postmarketing adverse reactions have been identified for inclusion in this section.

Tenofovir DF:

Immune System Disorders

allergic reaction, including angioedema

Metabolism and Nutrition Disorders

lactic acidosis, hypokalemia, hypophosphatemia

Respiratory, Thoracic, and Mediastinal Disorders

dyspnea

Gastrointestinal Disorders

pancreatitis, increased amylase, abdominal pain

Hepatobiliary Disorders

hepatic steatosis, hepatitis, increased liver enzymes (most commonly AST, ALT, gamma GT)

Skin and Subcutaneous Tissue Disorders

rash

Musculoskeletal and Connective Tissue Disorders

rhabdomyolysis, osteomalacia (manifested as bone pain and which may contribute to fractures), muscular weakness, myopathy

Renal and Urinary Disorders

acute renal failure, renal failure, acute tubular necrosis, Fanconi syndrome, proximal renal tubulopathy, interstitial nephritis (including acute cases), nephrogenic diabetes insipidus, renal insufficiency, increased creatinine, proteinuria, polyuria

General Disorders and Administration Site Conditions

asthenia

The following adverse reactions, listed under the body system headings above, may occur as a consequence of proximal renal tubulopathy: rhabdomyolysis, osteomalacia, hypokalemia, muscular weakness, myopathy, hypophosphatemia.

7 DRUG INTERACTIONS

7.1 Not Recommended with Other Antiretroviral Medications

Because COMPLERA is a complete regimen, coadministration with other antiretroviral medications for the treatment of HIV-1 infection is not recommended. Comprehensive information regarding potential drug-drug interactions with other antiretroviral medications is not provided.

This section describes clinically relevant drug interactions with COMPLERA. Drug interaction studies were conducted with the components of COMPLERA (FTC, RPV, and TDF as single agents) or with COMPLERA as a combination product [see *Dosage and Administration (2)*, *Contraindications (4)*, and *Clinical Pharmacology (12.3)*].

7.2 Drugs Inducing or Inhibiting CYP3A Enzymes

Rilpivirine is primarily metabolized by cytochrome P450 (CYP) 3A, and drugs that induce or inhibit CYP3A may thus affect the clearance of RPV [see *Contraindications (4)*, *Warnings and Precautions (5.7)*, and *Clinical Pharmacology (12.3)*]. Coadministration of RPV and drugs that induce CYP3A may result in decreased plasma concentrations of RPV and loss of virologic response and possible resistance to RPV or to the class of NNRTIs. Coadministration of RPV and drugs that inhibit CYP3A may result in increased plasma concentrations of RPV.

7.3 Drugs Increasing Gastric pH

Coadministration of RPV with drugs that increase gastric pH may decrease plasma concentrations of RPV and loss of virologic response and possible resistance to RPV or to the class of NNRTIs. Use of RPV with proton pump inhibitors is contraindicated and use of RPV with H₂-receptor antagonists requires staggered administration [see *Contraindications (4)* and *Clinical Pharmacology (12.3)*].

7.4 Drugs Affecting Renal Function

Because FTC and tenofovir are primarily eliminated by the kidneys through a combination of glomerular filtration and active tubular secretion, coadministration of COMPLERA with

drugs that reduce renal function or compete for active tubular secretion may increase serum concentrations of FTC, tenofovir, and/or other renally eliminated drugs. Some examples of drugs that are eliminated by active tubular secretion include, but are not limited to, acyclovir, adefovir dipivoxil, cidofovir, ganciclovir, valacyclovir, valganciclovir, aminoglycosides (e.g., gentamicin), and high-dose or multiple NSAIDs [see *Warnings and Precautions (5.5)*].

7.5 QT Prolonging Drugs

There is limited information available on the potential for a pharmacodynamic interaction between RPV and drugs that prolong the QTc interval of the electrocardiogram. In a study of healthy subjects, 75 mg once daily and 300 mg once daily doses of RPV (3 times and 12 times the dose in COMPLERA) have been shown to prolong the QTc interval of the electrocardiogram [see *Warnings and Precautions (5.7)* and *Clinical Pharmacology (12.2)*]. Consider alternatives to COMPLERA when coadministered with a drug with a known risk of Torsade de Pointes.

7.6 Significant Drug Interactions

Important drug interaction information for COMPLERA is summarized in Table 4. The drug interactions described are based on studies conducted with FTC, RPV, or TDF as individual medications or with COMPLERA as a combination product, or are potential drug interactions [see *Clinical Pharmacology (12.3)*, *Tables 9–14*]. For list of contraindicated drugs, [see *Contraindications (4)*].

Table 4 Significant^a Drug Interactions

Concomitant Drug Class: Drug Name	Effect on Concentration^b	Clinical Comment
Antacids: antacids (e.g., aluminum, magnesium hydroxide, or calcium carbonate)	↔ RPV (antacids taken at least 2 hours before or at least 4 hours after RPV) ↓ RPV (concomitant intake)	Administer antacids at least 2 hours before or at least 4 hours after COMPLERA.
Anticonvulsants: carbamazepine oxcarbazepine phenobarbital phenytoin	↓ RPV	Coadministration is contraindicated due to potential for loss of virologic response and development of resistance.
Antimycobacterials: rifampin rifapentine	↓ RPV	Coadministration is contraindicated due to potential for loss of virologic response and development of resistance.

Concomitant Drug Class: Drug Name	Effect on Concentration^b	Clinical Comment
rifabutin	↓ RPV ^c	If COMPLERA is coadministered with rifabutin, an additional 25 mg tablet of RPV (Edurant) once per day is recommended to be taken concomitantly with COMPLERA and with a meal for the duration of rifabutin coadministration.
Azole Antifungal Agents: fluconazole itraconazole ketoconazole posaconazole voriconazole	↑ RPV ^{c,d} ↓ ketoconazole ^{c,d}	No dose adjustment is required when COMPLERA is coadministered with azole antifungal agents. Clinically monitor for breakthrough fungal infections when azole antifungals are coadministered with COMPLERA.
Glucocorticoid (systemic): dexamethasone (more than a single-dose treatment)	↓ RPV	Coadministration is contraindicated due to potential for loss of virologic response and development of resistance.
Hepatitis C Antiviral Agents: ledipasvir/sofosbuvir sofosbuvir/velpatasvir sofosbuvir/velpatasvir/ voxilaprevir	↑ tenofovir ^c	Patients receiving COMPLERA concomitantly with HARVONI [®] (ledipasvir/sofosbuvir), EPCLUSA [®] (sofosbuvir/velpatasvir), or VOSEVI [®] (sofosbuvir/velpatasvir/voxilaprevir) should be monitored for adverse reactions associated with TDF.
H₂-Receptor Antagonists: cimetidine famotidine nizatidine ranitidine	↔ RPV ^{c,d} (famotidine taken 12 hours before RPV or 4 hours after RPV) ↓ RPV ^{c,d} (famotidine taken 2 hours before RPV)	Administer H ₂ -receptor antagonists at least 12 hours before or at least 4 hours after COMPLERA.
Herbal Products: St John's wort (<i>Hypericum perforatum</i>)	↓ RPV	Coadministration is contraindicated due to potential for loss of virologic response and development of resistance.
Macrolide or Ketolide Antibiotics: clarithromycin erythromycin telithromycin	↑ RPV ↔ clarithromycin ↔ erythromycin ↔ telithromycin	Where possible, alternatives such as azithromycin should be considered.
Narcotic Analgesics: methadone	↓ R(-) methadone ^c ↓ S(+) methadone ^c ↔ RPV ^c ↔ methadone ^c (when used with tenofovir)	No dose adjustments are required when initiating coadministration of methadone with COMPLERA. However, clinical monitoring is recommended as methadone maintenance therapy may need to be adjusted in some patients.

Concomitant Drug Class: Drug Name	Effect on Concentration ^b	Clinical Comment
Proton Pump Inhibitors: e.g., dexlansoprazole esomeprazole lansoprazole omeprazole pantoprazole rabeprazole	↓ RPV	Coadministration is contraindicated due to potential for loss of virologic response and development of resistance.

- a. This table is not all inclusive.
- b. Increase = ↑; Decrease = ↓; No Effect = ↔
- c. The interaction was evaluated in a clinical study. All other drug-drug interactions shown are predicted.
- d. This interaction study has been performed with a dose higher than the recommended dose for RPV assessing the maximal effect on the coadministered drug. The dosing recommendation is applicable to the recommended dose of RPV 25 mg once daily.

7.7 Drugs with No Observed Interactions with COMPLERA

No clinically significant drug interactions have been observed between FTC and the following medications: famciclovir, ledipasvir/sofosbuvir, sofosbuvir/velpatasvir, sofosbuvir/velpatasvir/voxilaprevir, or TDF.

No clinically significant drug interactions have been observed between TDF and the following medications: entecavir, methadone, oral contraceptives, ribavirin, sofosbuvir, or tacrolimus in studies conducted in healthy subjects.

No clinically significant drug interactions have been observed between RPV and the following medications: acetaminophen, atorvastatin, chlorzoxazone, ethinyl estradiol, ledipasvir/sofosbuvir, norethindrone, sildenafil, simeprevir, sofosbuvir, sofosbuvir/velpatasvir, sofosbuvir/velpatasvir/voxilaprevir, or TDF. RPV did not have a clinically significant effect on the pharmacokinetics of digoxin or metformin.

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Pregnancy Exposure Registry

There is a pregnancy exposure registry that monitors pregnancy outcomes in individuals exposed to COMPLERA during pregnancy. Healthcare providers are encouraged to register patients by calling the Antiretroviral Pregnancy Registry (APR) at 1-800-258-4263.

Risk Summary

Available data from the APR show no increase in the overall risk of major birth defects with first trimester exposure for emtricitabine (FTC), rilpivirine (RPV), or tenofovir (TDF) compared with the background rate for major birth defects of 2.7% in a U.S. reference

population of the Metropolitan Atlanta Congenital Defects Program (MACDP) (see *Data*). In a clinical trial, total rilpivirine exposures were generally lower during pregnancy compared to the postpartum period [see *Clinical Pharmacology (12.3)*]. The rate of miscarriage for individual drugs is not reported in the APR. The estimated background rate of miscarriage in clinically recognized pregnancies in the U.S. general population is 15-20%.

Based on the experience of HIV-1-infected pregnant individuals who completed a clinical trial through the postpartum period with an RPV-based regimen, no dose adjustments are required for pregnant patients who are already on a stable RPV-containing regimen prior to pregnancy and who are virologically suppressed (HIV-1 RNA less than 50 copies per mL). Lower exposures of RPV were observed during pregnancy, therefore viral load should be monitored closely [see *Data and Clinical Pharmacology (12.3)*].

In animal studies, no adverse developmental effects were observed when the components of COMPLERA were administered separately during the period of organogenesis at exposures up to 60 and 120 times (mice and rabbits, respectively, FTC) and 15 and 70 times (rats and rabbits, respectively; RPV) the exposure of these components in COMPLERA and at 14 and 19 times (rats and rabbits, respectively) the human dose of TDF based on body surface area comparisons (see *Data*). Likewise, no adverse developmental effects were seen when FTC was administered to mice and RPV was administered to rats through lactation at exposures up to approximately 60 and 63 times, respectively, the exposure at the recommended daily dose of these components in COMPLERA. No adverse effects were observed in the offspring of rats when TDF was administered through lactation at tenofovir exposures of approximately 14 times the exposure at the recommended daily dosage of COMPLERA.

Data

Human Data

Prospective reports from the APR of overall major birth defects in pregnancies exposed to drug components of COMPLERA are compared with a U.S. background major birth defect rate. Methodological limitations of the APR include the use of MACDP as the external comparator group. Limitations of using an external comparator include differences in methodology and populations, as well as confounding due to the underlying disease.

Emtricitabine: Based on prospective reports to the APR of exposures to FTC-containing regimens during pregnancy resulting in live births (including over 2,750 exposed in the first trimester and over 1,200 exposed in the second/third trimester), there was no increase in overall major birth defects with FTC compared with the background birth defect rate of 2.7% in the U.S. reference population of the MACDP. The prevalence of major birth defects in live births was 2.4% (95% CI: 1.9% to 3.1%) with first trimester exposure to FTC-containing regimens and 2.3% (95% CI: 1.5% to 3.3%) with the second/third trimester exposure to FTC-containing regimens.

Rilpivirine: RPV in combination with a background regimen was evaluated in a clinical trial of 19 HIV-1 infected pregnant subjects on an RPV-based regimen during the second and

third trimesters and postpartum. Each of the subjects were on an RPV-based regimen at the time of enrollment. Twelve subjects completed the trial through the postpartum period (6-12 weeks after delivery) and pregnancy outcomes are missing for six subjects. The exposure (C_{0h} and AUC) of total RPV was approximately 30 to 40% lower during pregnancy compared with postpartum (6 to 12 weeks). The protein binding of RPV was similar (>99%) during second trimester, third trimester, and postpartum period [see *Clinical Pharmacology (12.3)*]. One subject discontinued the trial following fetal death at 25 weeks gestation due to suspected premature rupture of membranes. Among the 12 subjects who were virologically suppressed at baseline (less than 50 copies/mL), virologic response was preserved in 10 subjects (83.3%) through the third trimester visit and in 9 subjects (75%) through the 6-12 week postpartum visit. Virologic outcomes during the third trimester visit were missing for two subjects who were withdrawn (one subject was nonadherent to the study drug and one subject withdrew consent). Among the 10 infants with available HIV test results, all were negative for HIV-1 at the time of delivery and up to 16 weeks postpartum (all 10 infants received prophylactic treatment with zidovudine). RPV was well tolerated during pregnancy and postpartum. There were no new safety findings compared with the known safety profile of RPV in HIV-1-infected adults.

Based on prospective reports to the APR of exposures to RPV-containing regimens during pregnancy (including over 290 exposed during first trimester and over 160 exposed in the second/third trimester), there was no significant increase in overall risk of major birth defects with RPV compared to the background birth defect rate of 2.7% in the U.S. reference population of the MACDP. The prevalence of major birth defects in live births was 1.0% (95% CI: 0.2% to 2.9%) and 1.2% (95% CI: 0.2% to 4.4%) following first and second/third trimester exposure, respectively, to RPV-containing regimens.

Tenofovir DF: Based on prospective reports to the APR of exposures to TDF-containing regimens during pregnancy resulting in live births (including over 3,500 exposed in the first trimester and over 1,500 exposed in the second/third trimester), there was no increase in overall risk of major birth defects compared with the background birth defect rate of 2.7% in the U.S. reference population of the MACDP. The prevalence of major birth defects in live births was 2.3% (95% CI: 1.8% to 2.9%) with first trimester exposure to TDF-containing regimens, and 2.2% (95% CI: 1.6% to 3.1%) with the second/third trimester exposure to TDF-containing regimens.

Animal Data

Emtricitabine: FTC was administered orally to pregnant mice (at 0, 250, 500, or 1,000 mg/kg/day), and rabbits (at 0, 100, 300, or 1,000 mg/kg/day) through organogenesis (on gestation days 6 through 15, and 7 through 19, respectively). No significant toxicological effects were observed in embryo-fetal toxicity studies performed with FTC in mice at exposures (AUC) approximately 60 times higher and in rabbits at approximately 120 times higher than human exposures at the recommended daily dose. In a pre/postnatal development study in mice, FTC was administered orally at doses up to 1,000 mg/kg/day; no significant adverse effects directly related to drug were observed in the offspring exposed daily from before birth (in utero) through sexual maturity at daily exposures

(AUC) of approximately 60 times higher than human exposures at the recommended daily dose.

Rilpivirine: RPV was administered orally to pregnant rats (40, 120, or 400 mg/kg/day) and rabbits (5, 10, or 20 mg/kg/day) through organogenesis (on gestation days 6 through 17, and 6 through 19, respectively). No significant toxicological effects were observed in embryo-fetal toxicity studies performed with RPV in rats and rabbits at exposures 15 (rats) and 70 (rabbits) times higher than the exposure in humans at the recommended dose of 25 mg once daily. In a pre/postnatal development study with RPV, where rats were administered up to 400 mg/kg/day through lactation, no significant adverse effects directly related to drug were noted in the offspring.

Tenofovir DF: TDF was administered orally to pregnant rats (at 0, 50, 150, or 450 mg/kg/day) and rabbits (at 0, 30, 100, or 300 mg/kg/day) through organogenesis (on gestation days 7 through 17, and 6 through 18, respectively). No significant toxicological effects were observed in embryo-fetal toxicity studies performed with TDF in rats at doses up to 14 times the human dose based on body surface area comparisons and in rabbits at doses up to 19 times the human dose based on body surface area comparisons. In a pre/postnatal development study in rats, TDF was administered orally through lactation at doses up to 600 mg/kg/day; no adverse effects were observed in the offspring at tenofovir exposures of approximately 2.7 times higher than human exposures at the recommended daily dose of COMPLERA.

8.2 Lactation

Risk Summary

The Centers for Disease Control and Prevention recommend that HIV infected mothers not breastfeed their infants to avoid risking postnatal transmission of HIV.

Based on published data, FTC and tenofovir have been shown to be present in human milk. There are no data on the presence of RPV in human milk. RPV has been shown to be present in rat milk (*see Data*).

It is not known if the components of COMPLERA affect milk production or have effects on the breastfed child. Because of the potential for: (1) HIV transmission (in HIV-negative infants); (2) developing viral resistance (in HIV-positive infants); and (3) adverse reactions in a breastfed infant similar to those seen in adults, instruct mothers not to breastfeed if they are receiving COMPLERA.

Data

Rilpivirine: In animals, no studies have been conducted to assess the excretion of RPV directly; however RPV was measured in rat pups which were exposed through the milk of treated dams (dosed up to 400 mg/kg/day).

8.4 Pediatric Use

The safety and effectiveness of COMPLERA as a complete regimen for the treatment of HIV-1 infection was established in pediatric subjects 12 years of age and older with body weight greater than or equal to 35 kg [see *Dosage and Administration (2.2)*]. Use of COMPLERA in this age group weighing at least 35 kg is supported by adequate and well-controlled studies of RPV+FTC+TDF in adults with HIV-1 infection as well as data from pediatric studies of the individual components of COMPLERA (RPV, FTC, and TDF) [see *Clinical Pharmacology (12.3)*, and *Clinical Studies (14.2)*].

COMPLERA should only be administered to pediatric patients with a body weight greater than or equal to 35 kg. Because COMPLERA is a fixed-dose combination tablet, the dose of COMPLERA cannot be adjusted for patients of lower weight. Safety and effectiveness for COMPLERA have not been established in pediatric patients weighing less than 35 kg [see *Adverse Reactions (6.1)* and *Clinical Pharmacology (12.3)*].

8.5 Geriatric Use

Clinical studies of FTC, RPV, or TDF did not include sufficient numbers of subjects aged 65 and over to determine whether they respond differently from younger subjects. In general, dose selection for elderly patients should be cautious, keeping in mind the greater frequency of decreased hepatic, renal, or cardiac function, and of concomitant disease or other drug therapy [see *Clinical Pharmacology (12.3)*].

8.6 Renal Impairment

Because COMPLERA is a fixed-dose combination, and cannot be dose adjusted, it is not recommended in patients with moderate, severe, or end-stage renal impairment (estimated creatinine clearance below 50 mL per minute) or that require dialysis [see *Warnings and Precautions (5.5)* and *Clinical Pharmacology (12.3)*].

8.7 Hepatic Impairment

No dose adjustment of COMPLERA is required in patients with mild (Child-Pugh Class A) or moderate (Child-Pugh Class B) hepatic impairment. COMPLERA has not been studied in patients with severe hepatic impairment (Child-Pugh Class C) [see *Clinical Pharmacology (12.3)*].

10 OVERDOSAGE

If overdose occurs the patient must be monitored for evidence of toxicity. Treatment of overdose with COMPLERA consists of general supportive measures, including monitoring of vital signs and ECG (QT interval) as well as observation of the clinical status of the patient.

Emtricitabine: Hemodialysis treatment removes approximately 30% of the FTC dose over a 3-hour dialysis period starting within 1.5 hours of FTC dosing (blood flow rate of 400 mL

per minute and a dialysate flow rate of 600 mL per minute). It is not known whether FTC can be removed by peritoneal dialysis.

Rilpivirine: There is no specific antidote for overdose with RPV. Human experience of overdose with RPV is limited. Since RPV is highly bound to plasma protein, dialysis is unlikely to result in significant removal of RPV.

Administration of activated charcoal may be used to aid in removal of unabsorbed active substance.

Tenofovir DF: Tenofovir is efficiently removed by hemodialysis with an extraction coefficient of approximately 54%. Following a single 300 mg dose of TDF, a 4-hour hemodialysis session removed approximately 10% of the administered tenofovir dose.

11 DESCRIPTION

COMPLERA is a fixed-dose combination tablet containing FTC, rilpivirine hydrochloride, and TDF. Emtricitabine (FTC) is a synthetic nucleoside analog of cytidine. Rilpivirine (RPV) is a non-nucleoside reverse transcriptase inhibitor. Tenofovir disoproxil fumarate (TDF) is converted in vivo to tenofovir, an acyclic nucleoside phosphonate (nucleotide) analog of adenosine 5'-monophosphate.

COMPLERA tablets are for oral administration. Each tablet contains 200 mg of FTC, 27.5 mg of rilpivirine hydrochloride (equivalent to 25 mg of RPV), and 300 mg of TDF (equivalent to 245 mg of tenofovir disoproxil) as active ingredients. The tablets include the following inactive ingredients: croscarmellose sodium, lactose monohydrate, magnesium stearate, microcrystalline cellulose, polysorbate 20, povidone, pregelatinized starch. The tablets are film coated with a coating material containing FD&C Blue #2 aluminum lake, FD&C Yellow #6 aluminum lake, hypromellose, iron oxide red, lactose monohydrate, polyethylene glycol, titanium dioxide, triacetin.

Emtricitabine: The chemical name of FTC is 5-fluoro-1-[(2*R*,5*S*)-2-(hydroxymethyl)-1,3-oxathiolan-5-yl]cytosine. Emtricitabine is the (-) enantiomer of a thio analog of cytidine, which differs from other cytidine analogs in that it has a fluorine in the 5-position.

It has a molecular formula of $C_8H_{10}FN_3O_3S$ and a molecular weight of 247.24. It has the following structural formula:

FTC is a white to off-white crystalline powder with a solubility of approximately 112 mg per mL in water at 25 °C.

Rilpivirine: RPV is available as the hydrochloride salt. The chemical name for rilpivirine hydrochloride is 4-[[4-[[4-[(*E*)-2-cyanoethenyl]-2,6-dimethylphenyl]amino]-2-pyrimidinyl]amino]benzotrile

e monohydrochloride. Its molecular formula is $C_{22}H_{18}N_6 \cdot HCl$ and its molecular weight is 402.88. Rilpivirine hydrochloride has the following structural formula:

Rilpivirine hydrochloride is a white to almost white powder. Rilpivirine hydrochloride is practically insoluble in water over a wide pH range.

Tenofovir DF: TDF is a fumaric acid salt of the bis-isopropoxycarbonyloxymethyl ester derivative of tenofovir. The chemical name of TDF is 9-[(*R*)-2 [[bis[[[(isopropoxycarbonyl)oxy]- methoxy]phosphinyl]methoxy]propyl]adenine fumarate (1:1). It has a molecular formula of $C_{19}H_{30}N_5O_{10}P \cdot C_4H_4O_4$ and a molecular weight of 635.52. It has the following structural formula:

TDF is a white to off-white crystalline powder with a solubility of 13.4 mg per mL in water at 25 °C. All dosages are expressed in terms of TDF except where otherwise noted.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

COMPLERA is a fixed-dose combination of the antiretroviral drugs FTC, RPV, and TDF [see *Microbiology (12.4)*].

12.2 Pharmacodynamics

Effects on Electrocardiogram

The effect of RPV at the recommended dose of 25 mg once daily on the QTcF interval was evaluated in a randomized, placebo-, and active- (moxifloxacin 400 mg once daily) controlled crossover study in 60 healthy adults, with 13 measurements over 24 hours at steady state. The maximum mean time-matched (95% upper confidence bound) differences in QTcF interval from placebo after baseline correction was 2.0 (5.0) milliseconds (i.e., below the threshold of clinical concern).

When doses of 75 mg once daily and 300 mg once daily of RPV (3 times and 12 times the dose in COMPLERA) were studied in healthy adults, the maximum mean time-matched

(95% upper confidence bound) differences in QTcF interval from placebo after baseline correction were 10.7 (15.3) and 23.3 (28.4) milliseconds, respectively. Steady-state administration of RPV 75 mg once daily and 300 mg once daily resulted in a mean steady-state C_{max} approximately 2.6-fold and 6.7-fold, respectively, higher than the mean C_{max} observed with the recommended 25 mg once daily dose of RPV [see *Warnings and Precautions* (5.7)].

12.3 Pharmacokinetics

COMPLERA: Under fed conditions (total calorie content of the meal was approximately 400 kcal with approximately 13 grams of fat), RPV, FTC, and tenofovir exposures were similar when comparing COMPLERA to EMTRIVA[®] capsules (200 mg) plus Edurant tablets (25 mg) plus VIREAD[®] tablets (300 mg) following single-dose administration to healthy subjects (N=34).

Single-dose administration of COMPLERA tablets to healthy subjects under fasted conditions provided approximately 25% higher exposure of RPV compared to administration of EMTRIVA capsules (200 mg) plus Edurant tablets (25 mg) plus VIREAD tablets (300 mg), while exposures of FTC and tenofovir were comparable (N=15).

Absorption, Distribution, Metabolism, and Excretion

The pharmacokinetic properties of the components of COMPLERA are provided in Table 5. The PK parameters of RPV, FTC, and tenofovir are provided in Table 6.

Table 5 Pharmacokinetic Properties of the Components of COMPLERA

	RPV	FTC	Tenofovir
Absorption			
T_{max} (h)	4-5	1-2	1
% Fasted oral bioavailability ^a	NC	93	25 ^f
Effect of a light meal (relative to fasting) ^b	↑9%	↔	↑28%
Effect of a standard meal (relative to fasting) ^b	↑16%	↔	↑38%
Distribution			
% Bound to human plasma proteins	~99	<4	<0.7
Source of protein binding data	In vitro	In vitro	In vitro
Metabolism			
Metabolism	CYP3A	Not significantly metabolized	
Elimination			
Major route of elimination	Metabolism	Glomerular filtration and active tubular secretion	
CL_{renal} ^c (mL/min)	NC	213±89	243±33
$t_{1/2}$ (h) ^d	50	10	17
% Of dose excreted in urine ^e	6	86	70–80
% Of dose excreted in feces ^e	85	~14	NC

NC=Not Calculated

- Median
- Values refer to % change based on calculated geometric mean ratio [fed/fasted] in AUC. COMPLERA light meal = 390 kcal, 12 g fat; COMPLERA standard meal = 540 kcal, 21 g fat. High fat meal not evaluated. Increase = ↑; Decrease = ↓; No Effect= ↔
- Mean ± SD
- $t_{1/2}$ values refer to median terminal plasma half-life.
- Dosing in mass balance studies: FTC (single dose administration of [^{14}C] FTC after multiple dosing of FTC for 10 days); RPV (single dose administration of [^{14}C] RPV); mass balance study not conducted for tenofovir.
- Oral bioavailability of tenofovir from VIREAD.

Table 6 Pharmacokinetic Parameters for RPV, FTC, and Tenofovir in HIV-Infected Adults

Parameter Mean ± SD	RPV ^a	FTC ^b	Tenofovir ^c
C_{\max} (µg/mL)	NA	1.80±0.72 ^d	0.30±0.09
AUC _{tau} (µg·hr/mL)	2.24±0.85 ^d	10.0±3.12 ^d	2.29±0.69 ^e
C_{0h} (µg/mL)	0.08±0.04 ^d	0.09±0.07 ^d	NA

NA=Not Applicable; SD=Standard Deviation

- Population PK estimates of RPV 25 mg once daily in antiretroviral treatment-naïve HIV-1-infected adult subjects (pooled data from Phase 3 trials through Week 96; n=679)
- Multiple-dose oral administration of FTC 200 mg to HIV-1-infected subjects (n=20)
- Single 300 mg dose of TDF to HIV-1-infected subjects in the fasted state
- Data presented as steady state values
- AUC_{0-24h}

Specific Populations

Geriatric Patients

The pharmacokinetics of FTC, RPV, and tenofovir have not been fully evaluated in the elderly (65 years of age and older) [see *Use in Specific Populations (8.5)*].

Pediatric Patients

Pediatric trials have not been conducted using COMPLERA tablets. Pediatric information is based on trials conducted with the individual components of COMPLERA [see *Use in Specific Populations (8.4)*].

Emtricitabine: The pharmacokinetics of FTC at steady state were determined in 27 HIV-1-infected pediatric subjects 13 to 17 years of age receiving a daily dose of 6 mg/kg up to a maximum dose of 240 mg oral solution or a 200 mg capsule; 26 of 27 subjects in this age group received the 200 mg FTC capsule. Mean (± SD) C_{\max} and AUC were 2.7 ± 0.9 µg/mL and 12.6 ± 5.4 µg·hr/mL, respectively. Exposures achieved in pediatric subjects 12 to less than 18 years of age were similar to those achieved in adults receiving a once daily dose of 200 mg.

Rilpivirine: The pharmacokinetics of RPV in antiretroviral treatment-naïve HIV-1- infected pediatric subjects 12 to less than 18 years of age receiving RPV 25 mg once daily were comparable to those in treatment-naïve HIV-1-infected adults receiving RPV 25 mg once daily (See Table 7). There was no clinically significant impact of body weight on RPV pharmacokinetics in pediatric subjects in trial C213 (33 to 93 kg).

Table 7 Population Pharmacokinetic Estimates of RPV 25 mg once daily in Antiretroviral Treatment-Naïve HIV-1-Infected Pediatric Subjects aged 12 to less than 18 years (Data from Phase 2 Trial through Week 48)

Parameter	RPV 25 mg once daily N=34
AUC _{24h} (ng•h/mL)	
Mean ± Standard Deviation	2424 ± 1024
Median (Range)	2269 (417–5166)
C _{0h} (ng/mL)	
Mean ± Standard Deviation	85 ± 40
Median (Range)	79 (7–202)

Tenofovir DF: Steady-state pharmacokinetics of tenofovir were evaluated in 8 HIV-1-infected pediatric subjects (12 to less than 18 years). Mean (\pm SD) C_{max} and AUC_{tau} are 0.38 \pm 0.13 μ g/mL and 3.39 \pm 1.22 μ g•hr/mL, respectively. Tenofovir exposure achieved in these pediatric subjects receiving oral daily doses of TDF 300 mg was similar to exposures achieved in adults receiving once-daily doses of TDF 300 mg.

Gender

No clinically relevant pharmacokinetic differences have been observed based on gender for FTC, RPV, and TDF.

Race

Emtricitabine: No pharmacokinetic differences due to race have been identified following the administration of FTC.

Rilpivirine: Population pharmacokinetic analysis of RPV in HIV-1-infected subjects indicated that race had no clinically relevant effect on the exposure to RPV.

Tenofovir DF: There were insufficient numbers from racial and ethnic groups other than Caucasian to adequately determine potential pharmacokinetic differences among these populations following the administration of TDF.

Patients with Renal Impairment

Emtricitabine and Tenofovir DF: The pharmacokinetics of FTC and TDF are altered in subjects with renal impairment. In subjects with creatinine clearance below 50 mL per minute or with end stage renal disease requiring dialysis, C_{max} and AUC of FTC and tenofovir were increased [see *Warnings and Precautions (5.5) and Use in Specific Populations (8.6)*].

Rilpivirine: Population pharmacokinetic analysis indicated that RPV exposure was similar in HIV-1-infected subjects with mild renal impairment relative to HIV-1-infected subjects with normal renal function. There is limited or no information regarding the pharmacokinetics of RPV in patients with moderate or severe renal impairment or in patients with end-stage renal disease, and RPV concentrations may be increased due to alteration of drug absorption, distribution, and metabolism secondary to renal dysfunction [see *Use in Specific Populations (8.6)*].

Patients with Hepatic Impairment

Emtricitabine: The pharmacokinetics of FTC have not been studied in subjects with hepatic impairment; however, FTC is not significantly metabolized by liver enzymes, so the impact of liver impairment should be limited.

Rilpivirine: RPV is primarily metabolized and eliminated by the liver. In a study comparing 8 subjects with mild hepatic impairment (Child-Pugh score A) to 8 matched controls, and 8 subjects with moderate hepatic impairment (Child-Pugh score B) to 8 matched controls, the multiple dose exposure of RPV was 47% higher in subjects with mild hepatic impairment and 5% higher in subjects with moderate hepatic impairment. RPV has not been studied in subjects with severe hepatic impairment (Child-Pugh score C) [see *Use in Specific Populations (8.7)*].

Tenofovir DF: The pharmacokinetics of tenofovir following a 300 mg dose of TDF have been studied in non-HIV-infected subjects with moderate to severe hepatic impairment. There were no substantial alterations in tenofovir pharmacokinetics in subjects with hepatic impairment compared with unimpaired subjects.

Hepatitis B and/or Hepatitis C Virus Coinfection

The pharmacokinetics of FTC and TDF have not been fully evaluated in hepatitis B and/or C virus-coinfected patients. Population pharmacokinetic analysis indicated that hepatitis B and/or C virus coinfection had no clinically relevant effect on the exposure to RPV.

Pregnancy and Postpartum

The exposure (C_{0h} and AUC_{24h}) to total RPV after intake of RPV 25 mg once daily as part of an antiretroviral regimen was 30 to 40% lower during pregnancy (similar for the second and third trimester), compared with postpartum (see Table 8). However, the exposure during pregnancy was not significantly different from exposures obtained in Phase 3 trials of RPV-containing regimens. Based on the exposure-response relationship for RPV, this decrease is not considered clinically relevant in patients who are virologically suppressed. The protein binding of RPV was similar (>99%) during the second trimester, third trimester, and postpartum.

Table 8: Pharmacokinetic Results of Total RPV After Administration of RPV 25 mg Once Daily as Part of an Antiretroviral Regimen, During the 2nd Trimester of Pregnancy, the 3rd Trimester of Pregnancy and Postpartum

Pharmacokinetics of total RPV (mean \pm SD, t_{max} : median [range])	Postpartum (6-12 Weeks) (n=11)	2 nd Trimester of pregnancy (n=15)	3 rd Trimester of pregnancy (n=13)
C_{0h} , ng/mL	111 \pm 69.2	65.0 \pm 23.9	63.5 \pm 26.2
C_{min} , ng/mL	84.0 \pm 58.8	54.3 \pm 25.8	52.9 \pm 24.4
C_{max} , ng/mL	167 \pm 101	121 \pm 45.9	123 \pm 47.5
t_{max} , h	4.00 (2.03-25.08)	4.00 (1.00-9.00)	4.00 (2.00-24.93)
AUC_{24h} , ng.h/mL	2,714 \pm 1,535	1,792 \pm 711	1,762 \pm 662

Drug Interaction Studies

Rilpivirine: RPV is primarily metabolized by cytochrome CYP3A, and drugs that induce or inhibit CYP3A may thus affect the clearance of RPV. Coadministration of COMPLERA and drugs that induce CYP3A may result in decreased plasma concentrations of RPV and loss of virologic response and possible resistance. Coadministration of COMPLERA and drugs that inhibit CYP3A may result in increased plasma concentrations of RPV. Coadministration of COMPLERA with drugs that increase gastric pH may result in decreased plasma concentrations of RPV and loss of virologic response and possible resistance to RPV and to the class of NNRTIs.

RPV at a dose of 25 mg once daily is not likely to have a clinically relevant effect on the exposure of medicinal products metabolized by CYP enzymes.

Emtricitabine and Tenofovir DF: In vitro and clinical pharmacokinetic drug-drug interaction studies have shown that the potential for CYP-mediated interactions involving FTC and tenofovir with other medicinal products is low.

FTC and tenofovir are primarily excreted by the kidneys by a combination of glomerular filtration and active tubular secretion. No drug-drug interactions due to competition for renal excretion have been observed; however, coadministration of FTC and TDF with drugs that are eliminated by active tubular secretion may increase concentrations of FTC, tenofovir, and/or the coadministered drug [see *Drug Interactions (7.4, 7.6)*].

Drugs that decrease renal function may increase concentrations of FTC and/or tenofovir.

The drug interaction studies described in Tables 9-14 were conducted with COMPLERA (RPV/FTC/TDF) or the components of COMPLERA (RPV, FTC, or TDF) administered individually.

The effects of coadministration of other drugs on the AUC, C_{max} , and C_{min} values of RPV, FTC, and TDF are summarized in Tables 9, 10, and 11, respectively. The effect of coadministration of RPV, FTC, and TDF on the AUC, C_{max} , and C_{min} values of other drugs are summarized in Tables 12, 13, and 14, respectively. For information regarding clinical recommendations, see *Drug Interactions (7)*.

Table 9 Drug Interactions: Changes in Pharmacokinetic Parameters for RPV in the Presence of the Coadministered Drugs

Coadministered Drug	Dose of Coadministered Drug (mg)	RPV Dose (mg)	N ^a	Mean % Change of RPV Pharmacokinetic Parameters ^b (90% CI)

b. Increase = ↑; No Effect = ↔

No effect on the pharmacokinetic parameters of the following coadministered drugs was observed with TDF: methadone, oral contraceptives (ethinyl estradiol/norgestimate), or ribavirin.

12.4 Microbiology

Mechanism of Action

Emtricitabine: FTC, a synthetic nucleoside analog of cytidine, is phosphorylated by cellular enzymes to form emtricitabine 5'-triphosphate. Emtricitabine 5'-triphosphate inhibits the activity of the HIV-1 RT by competing with the natural substrate deoxycytidine

5'-triphosphate and by being incorporated into nascent viral DNA, which results in chain termination. Emtricitabine 5'-triphosphate is a weak inhibitor of mammalian DNA polymerases α , β , ϵ , and mitochondrial DNA polymerase γ .

Rilpivirine: RPV is a diarylpyrimidine non-nucleoside reverse transcriptase inhibitor of HIV-1 and inhibits HIV-1 replication by non-competitive inhibition of HIV-1 RT. RPV does not inhibit the human cellular DNA polymerases α , β , and mitochondrial DNA polymerase γ .

Tenofovir DF: TDF is an acyclic nucleoside phosphonate diester analog of adenosine monophosphate. TDF requires initial diester hydrolysis for conversion to tenofovir and subsequent phosphorylations by cellular enzymes to form tenofovir diphosphate. Tenofovir diphosphate inhibits the activity of HIV-1 RT by competing with the natural substrate deoxyadenosine 5'-triphosphate and, after incorporation into DNA, by DNA chain termination. Tenofovir diphosphate is a weak inhibitor of mammalian DNA polymerases α , β , and mitochondrial DNA polymerase γ .

Antiviral Activity

Emtricitabine, Rilpivirine, and TDF: The triple combination of FTC, RPV, and TDF was not antagonistic in cell culture.

Emtricitabine: The antiviral activity of FTC against laboratory and clinical isolates of HIV-1 was assessed in lymphoblastoid cell lines, the MAGI-CCR5 cell line, and peripheral blood mononuclear cells. The 50% effective concentration (EC_{50}) values for FTC were in the range of 0.0013–0.64 μ M. FTC displayed antiviral activity in cell culture against HIV-1 clades A, B, C, D, E, F, and G (EC_{50} values ranged from 0.007–0.075 μ M) and showed strain specific activity against HIV-2 (EC_{50} values ranged from 0.007–1.5 μ M). In drug combination studies of FTC with nucleoside reverse transcriptase inhibitors (abacavir, lamivudine, stavudine, tenofovir, zidovudine), non-nucleoside reverse transcriptase inhibitors (delavirdine, EFV, nevirapine, and RPV), and protease inhibitors (amprenavir, nelfinavir, ritonavir, saquinavir), no antagonistic effects were observed.

Rilpivirine: RPV exhibited activity against laboratory strains of wild-type HIV-1 in an acutely infected T-cell line with a median EC_{50} value for HIV-1_{III B} of 0.73 nM. RPV demonstrated limited activity in cell culture against HIV-2 with a median EC_{50} value of 5220 nM (range 2510–10,830 nM). RPV demonstrated antiviral activity against a broad panel of HIV-1 group M (subtype A, B, C, D, F, G, H) primary isolates with EC_{50} values ranging from 0.07–1.01 nM and was less active against group O primary isolates with EC_{50} values ranging from 2.88–8.45 nM. The antiviral activity of RPV was not antagonistic when combined with the NNRTIs EFV, etravirine, or nevirapine; the N(t)RTIs abacavir, didanosine, FTC, lamivudine, stavudine, tenofovir, or zidovudine; the PIs amprenavir, atazanavir, darunavir, indinavir, lopinavir, nelfinavir, ritonavir, saquinavir, or tipranavir; the gp41 fusion inhibitor enfuvirtide; the CCR5 co-receptor antagonist maraviroc; or the integrase strand transfer inhibitor raltegravir.

Tenofovir DF: The antiviral activity of tenofovir against laboratory and clinical isolates of HIV-1 was assessed in lymphoblastoid cell lines, primary monocyte/macrophage cells,

and peripheral blood lymphocytes. The EC₅₀ values for tenofovir were in the range of 0.04–8.5 μM. Tenofovir displayed antiviral activity in cell culture against HIV-1 clades A, B, C, D, E, F, G, and O (EC₅₀ values ranged from 0.5–2.2 μM) and showed strain specific activity against HIV-2 (EC₅₀ values ranged from 1.6–5.5 μM). In drug combination studies of tenofovir with NRTIs (abacavir, didanosine, FTC, lamivudine, stavudine, and zidovudine), NNRTIs (delavirdine, EFV, nevirapine, and RPV), and PIs (amprenavir, indinavir, nelfinavir, ritonavir, saquinavir), no antagonistic effects were observed.

Resistance

In Cell Culture

Emtricitabine and Tenofovir DF: HIV-1 isolates with reduced susceptibility to FTC or tenofovir have been selected in cell culture. Reduced susceptibility to FTC was associated with M184V/I substitutions in HIV-1 RT. HIV-1 isolates selected by tenofovir expressed a K65R substitution in HIV-1 RT and showed a 2–4 fold reduction in susceptibility to tenofovir. In addition, a K70E substitution in HIV-1 RT has been selected by tenofovir and results in low-level reduced susceptibility to abacavir, FTC, lamivudine, and tenofovir.

Rilpivirine: RPV-resistant strains were selected in cell culture starting from wild-type HIV-1 of different origins and subtypes as well as NNRTI-resistant HIV-1. The frequently observed amino acid substitutions that emerged and conferred decreased phenotypic susceptibility to RPV included: L100I, K101E, V106I and A, V108I, E138K and G, Q, R, V179F and I, Y181C and I, V189I, G190E, H221Y, F227C, and M230I and L.

In HIV-1-Infected Adult Subjects With No Antiretroviral Treatment History

In the Week 96 pooled resistance analysis for adult subjects receiving RPV or EFV in combination with FTC/TDF in the Phase 3 clinical trials C209 and C215, the emergence of resistance was greater among subjects' viruses in the RPV + FTC/TDF arm compared to the EFV + FTC/TDF arm and was dependent on baseline viral load. In the pooled resistance analysis, 61% (47/77) of the subjects who qualified for resistance analysis (resistance analysis subjects) in the RPV + FTC/TDF arm had virus with genotypic and/or phenotypic resistance to RPV compared to 42% (18/43) of the resistance analysis subjects in the EFV + FTC/TDF arm who had genotypic and/or phenotypic resistance to EFV. Moreover, genotypic and/or phenotypic resistance to FTC or tenofovir emerged in viruses from 57% (44/77) of the resistance analysis subjects in the RPV arm compared to 26% (11/43) in the EFV arm.

Emerging NNRTI substitutions in the RPV resistance analysis of subjects' viruses included V90I, K101E/P/T, E138K/A/Q/G, V179I/L, Y181C/I, V189I, H221Y, F227C/L, and M230L, which were associated with an RPV phenotypic fold change range of 2.6–621. The E138K substitution emerged most frequently during RPV treatment, commonly in combination with the M184I substitution. The FTC and lamivudine resistance-associated substitutions M184I or V and NRTI resistance-associated substitutions (K65R/N, A62V, D67N/G, K70E, Y115F, K219E/R) emerged more frequently in the RPV resistance analysis subjects than in EFV resistance analysis subjects (See Table 15).

NNRTI- and NRTI-resistance substitutions emerged less frequently in the resistance analysis of viruses from subjects with baseline viral loads of $\leq 100,000$ copies/mL compared to viruses from subjects with baseline viral loads of $> 100,000$ copies/mL: 23% (10/44) compared to 77% (34/44) of NNRTI-resistance substitutions and 20% (9/44) compared to 80% (35/44) of NRTI-resistance substitutions. This difference was also observed for the individual FTC/lamivudine and tenofovir resistance substitutions: 22% (9/41) compared to 78% (32/41) for M184I/V and 0% (0/8) compared to 100% (8/8) for K65R/N. Additionally, NNRTI and/or NRTI-resistance substitutions emerged less frequently in the resistance analysis of the viruses from subjects with baseline CD4+ cell counts ≥ 200 cells/mm³ compared to the viruses from subjects with baseline CD4+ cell counts < 200 cells/mm³: 32% (14/44) compared to 68% (30/44) of NNRTI-resistance substitutions and 27% (12/44) compared to 73% (32/44) of NRTI-resistance substitutions.

Table 15 Proportion of Frequently Emerging Reverse Transcriptase Substitutions in the HIV-1 Virus of Resistance Analysis Adult Subjects^a Who Received RPV or EFV in Combination with FTC/TDF from Pooled Phase 3 TMC278-C209 and TMC278-C215 Trials in the Week 96 Analysis

In Virologically Suppressed HIV-1-Infected Adult Subjects

Study 106: Through Week 48, 4 subjects who switched to COMPLERA (4 of 469 subjects, 0.9%) and 1 subject who maintained their ritonavir-boosted protease inhibitor-based regimen (1 of 159 subjects, 0.6%) developed genotypic and/or phenotypic resistance to a study drug. All 4 of the subjects who had resistance emergence on COMPLERA had evidence of FTC resistance and 3 of the subjects had evidence of RPV resistance.

Cross Resistance

Rilpivirine, Emtricitabine, and Tenofovir DF:

In Cell Culture

No significant cross-resistance has been demonstrated between RPV-resistant HIV-1 variants and FTC or tenofovir, or between FTC- or tenofovir-resistant variants and RPV.

Rilpivirine:

Site-Directed NNRTI Mutant Virus

Cross-resistance has been observed among NNRTIs. The single NNRTI substitutions K101P, Y181I, and Y181V conferred 52-fold, 15-fold, and 12-fold decreased susceptibility to RPV, respectively. The combination of E138K and M184I showed 6.7-fold reduced susceptibility to RPV compared to 2.8-fold for E138K alone. The K103N substitution did not show reduced susceptibility to RPV by itself. However, the combination of K103N and L100I resulted in a 7-fold reduced susceptibility to RPV. In another study, the Y188L substitution resulted in a reduced susceptibility to RPV of 9-fold for clinical isolates and 6-fold for site-directed mutants. Combinations of 2 or 3 NNRTI

resistance-associated substitutions gave decreased susceptibility to RPV (fold change range of 3.7–554) in 38% and 66% of mutants, respectively.

In HIV-1-Infected Adult Subjects With No Antiretroviral Treatment History

Considering all available cell culture and clinical data, any of the following amino acid substitutions, when present at baseline, are likely to decrease the antiviral activity of RPV: K101E, K101P, E138A, E138G, E138K, E138R, E138Q, V179L, Y181C, Y181I, Y181V, Y188L, H221Y, F227C, M230I, M230L, and the combination of L100I+K103N.

Cross-resistance to EFV, etravirine, and/or nevirapine is likely after virologic failure and development of RPV resistance. In a pooled 96-week analysis for adult subjects receiving RPV in combination with FTC/TDF in the Phase 3 clinical trials TMC278-C209 and TMC278-C215, 43 of the 70 (61%) RPV resistance analysis subjects with postbaseline resistance data had virus with decreased susceptibility to RPV (≥ 2.5 fold change). Of these, 84% ($n=36/43$) were resistant to EFV (≥ 3.3 -fold change), 88% ($n=38/43$) were resistant to etravirine (≥ 3.2 -fold change), and 60% ($n=26/43$) were resistant to nevirapine (≥ 6 -fold change). In the EFV arm, 3 of the 15 (20%) EFV resistance analysis subjects had viruses with resistance to etravirine and RPV, and 93% (14/15) had resistance to nevirapine. Virus from subjects experiencing virologic failure on RPV in combination with FTC/TDF developed more NNRTI resistance-associated substitutions conferring more cross-resistance to the NNRTI class and had a higher likelihood of cross-resistance to all NNRTIs in the class than subjects who failed on EFV.

Emtricitabine: FTC-resistant isolates (M184V/I) were cross-resistant to lamivudine but retained susceptibility in cell culture to didanosine, stavudine, tenofovir, zidovudine, and NNRTIs (delavirdine, EFV, nevirapine, and RPV). HIV-1 isolates containing the K65R substitution, selected in vivo by abacavir, didanosine, and tenofovir, demonstrated reduced susceptibility to inhibition by FTC. Viruses harboring substitutions conferring reduced susceptibility to stavudine and zidovudine (M41L, D67N, K70R, L210W, T215Y/F, K219Q/E), or didanosine (L74V), remained sensitive to FTC. HIV-1 containing the substitutions associated with NNRTI resistance K103N or RPV-associated substitutions were susceptible to FTC.

Tenofovir DF: The K65R and K70E substitutions selected by tenofovir are also selected in some HIV-1-infected patients treated with abacavir or didanosine. HIV-1 isolates with the K65R and K70E substitutions also showed reduced susceptibility to FTC and lamivudine. Therefore, cross-resistance among these NRTIs may occur in patients whose virus harbors the K65R substitution. HIV-1 isolates from patients ($N=20$) whose HIV-1 expressed a mean of 3 zidovudine-associated RT amino acid substitutions (M41L, D67N, K70R, L210W, T215Y/F, or K219Q/E/N) showed a 3.1-fold decrease in the susceptibility to tenofovir.

Subjects whose virus expressed an L74V substitution without zidovudine resistance-associated substitutions ($N=8$) had reduced response to TDF. Limited data are available for patients whose virus expressed a Y115F substitution ($N=3$), Q151M substitution ($N=2$), or T69 insertion ($N=4$), all of whom had a reduced response.

HIV-1 containing the substitutions associated with NNRTI resistance K103N and Y181C, or RPV-associated substitutions, were susceptible to tenofovir.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Emtricitabine: In long-term carcinogenicity studies of FTC, no drug-related increases in tumor incidence were found in mice at doses up to 750 mg per kg per day (26 times the human systemic exposure at the therapeutic dose of 200 mg per day) or in rats at doses up to 600 mg per kg per day (31 times the human systemic exposure at the therapeutic dose).

FTC was not genotoxic in the reverse mutation bacterial test (Ames test), or the mouse lymphoma or mouse micronucleus assays.

FTC did not affect fertility in male rats at approximately 140-fold or in male and female mice at approximately 60-fold higher exposures (AUC) than in humans given the recommended 200 mg daily dose. Fertility was normal in the offspring of mice exposed daily from before birth (in utero) through sexual maturity at daily exposures (AUC) of approximately 60-fold higher than human exposures at the recommended 200 mg daily dose.

Rilpivirine: RPV was evaluated for carcinogenic potential by oral gavage administration to mice and rats up to 104 weeks. Daily doses of 20, 60, and 160 mg per kg per day were administered to mice and doses of 40, 200, 500, and 1500 mg per kg per day were administered to rats. In rats, there were no drug-related neoplasms. In mice, RPV was positive for hepatocellular neoplasms in both males and females. The observed hepatocellular findings in mice may be rodent-specific. At the lowest tested doses in the carcinogenicity studies, the systemic exposures (based on AUC) to RPV were 21 fold (mice) and 3 fold (rats), relative to those observed in humans at the recommended dose (25 mg once daily).

RPV has tested negative in the absence and presence of a metabolic activation system, in the in vitro Ames reverse mutation assay and in vitro clastogenicity mouse lymphoma assay. RPV did not induce chromosomal damage in the in vivo micronucleus test in mice.

In a study conducted in rats, there were no effects on mating or fertility with RPV up to 400 mg per kg per day, a dose of RPV that showed maternal toxicity. This dose is associated with an exposure that is approximately 40 times higher than the exposure in humans at the recommended dose of 25 mg once daily.

Tenofovir DF: Long-term oral carcinogenicity studies of TDF in mice and rats were carried out at exposures up to approximately 16 times (mice) and 5 times (rats) those observed in humans at the therapeutic dose for HIV-1 infection. At the high dose in female mice, liver adenomas were increased at exposures 16 times that in humans. In rats, the study was negative for carcinogenic findings at exposures up to 5 times that observed in humans at the therapeutic dose.

Tenofovir DF was mutagenic in the in vitro mouse lymphoma assay and negative in an in vitro bacterial mutagenicity test (Ames test). In an in vivo mouse micronucleus assay, TDF was negative when administered to male mice.

There were no effects on fertility, mating performance, or early embryonic development when TDF was administered to male rats at a dose equivalent to 10 times the human dose based on body surface area comparisons for 28 days prior to mating and to female rats for 15 days prior to mating through day 7 of gestation. There was, however, an alteration of the estrous cycle in female rats.

13.2 Animal Toxicology and/or Pharmacology

Tenofovir DF: Tenofovir and TDF administered in toxicology studies to rats, dogs, and monkeys at exposures (based on AUCs) greater than or equal to 6-fold those observed in humans caused bone toxicity. In monkeys the bone toxicity was diagnosed as osteomalacia. Osteomalacia observed in monkeys appeared to be reversible upon dose reduction or discontinuation of tenofovir. In rats and dogs, the bone toxicity manifested as reduced bone mineral density. The mechanism(s) underlying bone toxicity is unknown.

Evidence of renal toxicity was noted in 4 animal species. Increases in serum creatinine, BUN, glycosuria, proteinuria, phosphaturia, and/or calciuria and decreases in serum phosphate were observed to varying degrees in these animals. These toxicities were noted at exposures (based on AUCs) 2–20 times higher than those observed in humans. The relationship of the renal abnormalities, particularly the phosphaturia, to the bone toxicity is not known.

14 CLINICAL STUDIES

14.1 Adult Subjects

In HIV-1-Infected Adult Subjects With No Antiretroviral Treatment History

The efficacy of COMPLERA is based on the analyses of 48- and 96-week data from two randomized, double-blind, controlled studies (Study C209 [ECHO] and TRUVADA subset of Study C215 [THRIVE]) in treatment-naïve, HIV-1-infected subjects (N=1368). The studies are identical in design with the exception of the background regimen (BR). Subjects were randomized in a 1:1 ratio to receive either RPV 25 mg (N=686) once daily or EFV 600 mg (N=682) once daily in addition to a BR. In Study C209 (N=690), the BR was FTC/TDF. In Study C215 (N=678), the BR consisted of 2 NRTIs: FTC/TDF (60%, n=406), lamivudine/zidovudine (30%, n=204), or abacavir + lamivudine (10%, n=68).

For subjects who received FTC/TDF (N=1096) in studies C209 and C215, the mean age was 37 years (range 18–78), 78% were male, 62% were White, 24% were Black, and 11% were Asian. The mean baseline CD4+ cell count was 265 cells/mm³ (range 1–888) and 31% had CD4+ cell counts <200 cells/mm³. The median baseline plasma HIV-1 RNA was 5 log₁₀ copies/mL (range 2–7). Subjects were stratified by baseline HIV-1 RNA. Fifty percent of subjects had baseline viral load ≤100,000 copies/mL, 39% of subjects had

baseline viral load between 100,000 copies/mL to 500,000 copies/mL, and 11% of subjects had baseline viral load >500,000 copies/mL.

Treatment outcomes through 96 weeks for the subset of subjects receiving FTC/TDF in studies C209 and C215 (Table 16) are generally consistent with treatment outcomes for all participating subjects (presented in the prescribing information for Edurant). The incidence of virologic failure was higher in the RPV arm than the EFV arm at Week 96. Virologic failures and discontinuations due to adverse events mostly occurred in the first 48 weeks of treatment.

Table 16 Pooled Virologic Outcome of Randomized Treatment of Studies C209 and C215 at Week 96 in Adult Subjects With No Antiviral Treatment History in Combination with FTC/TDF at Week 96^a

	RPV + FTC/TDF	EFV + FTC/TDF
	N=550	N=546
HIV-1 RNA <50 copies/mL^b	77%	77%
HIV-1 RNA ≥50 copies/mL^c	14%	8%
No Virologic Data at Week 96 Window		
Reasons		
Discontinued study due to adverse event or death ^d	4%	9%
Discontinued study for other reasons ^e and the last available HIV-1 RNA <50 copies/mL (or missing)	4%	6%
Missing data during window but on study	<1%	<1%
HIV-1 RNA <50 copies/mL by Baseline HIV-1 RNA (copies/mL)		
≤100,000	83%	80%
>100,000	71%	74%
HIV-1 RNA ≥50 copies/mL^c by Baseline HIV-1 RNA (copies/mL)		
≤100,000	7%	5%
>100,000	22%	12%
HIV-1 RNA <50 copies/mL by Baseline CD4+ Cell Count (cells/mm³)		
<200	68%	72%
≥200	82%	79%
HIV-1 RNA ≥50 copies/mL^c by Baseline CD4+ Cell Count (cells/mm³)		
<200	27%	12%
≥200	8%	7%

a. Analyses were based on the last observed viral load data within the Week 96 window (Week 90–103).

- b. Predicted difference (95% CI) of response rate is 0.5% (–4.5% to 5.5%) at Week 96.
- c. Includes subjects who had ≥ 50 copies/mL in the Week 96 window, subjects who discontinued early due to lack or loss of efficacy, subjects who discontinued for reasons other than an adverse event, death, or lack or loss of efficacy and at the time of discontinuation had a viral load value of ≥ 50 copies/mL, and subjects who had a switch in background regimen that was not permitted by the protocol.
- d. Includes subjects who discontinued due to an adverse event or death if this resulted in no on-treatment virologic data in the Week 96 window.
- e. Includes subjects who discontinued for reasons other than an adverse event, death, or lack or loss of efficacy, e.g., withdrew consent, loss to follow-up, etc.

Based on the pooled data from studies C209 and C215, the mean CD4+ cell count increase from baseline at Week 96 was 226 cells/mm³ for RPV + FTC/TDF-treated subjects and 223 cells/mm³ for EFV + FTC/TDF-treated subjects.

In Virologically Suppressed HIV-1-Infected Adult Subjects

The efficacy and safety of switching from a ritonavir-boosted protease inhibitor in combination with two NRTIs to COMPLERA was evaluated in Study 106, a randomized, open-label study in virologically suppressed HIV-1-infected adults. Subjects had to be on either their first or second antiretroviral regimen with no history of virologic failure, have no current or past history of resistance to any of the three components of COMPLERA, and must have been suppressed (HIV-1 RNA <50 copies/mL) for at least 6 months prior to screening. Subjects were randomized in a 2:1 ratio to either switch to COMPLERA at baseline (COMPLERA arm, N=317), or stay on their baseline antiretroviral regimen for 24 weeks (SBR arm, N=159) and then switch to COMPLERA for an additional 24 weeks (N=52). Subjects had a mean age of 42 years (range 19–73), 88% were male, 77% were White, 17% were Black, and 17% were Hispanic/Latino. The mean baseline CD4+ cell count was 584 cells/mm³ (range 42–1484). Randomization was stratified by use of TDF and/or lopinavir/ritonavir in the baseline regimen.

Treatment outcomes are presented in Table 17.

Table 17 Virologic Outcomes of Study GS-US-264-0106 in Virologically Suppressed Subjects

	COMPLERA	Stayed on Baseline Regimen (SBR)
	Week 48 ^a	Week 24 ^b
	N=317	N=159
HIV-1 RNA <50 copies/mL ^c	89% (283/317)	90% (143/159)
HIV-1 RNA ≥50 copies/mL ^d	3% (8/317)	5% (8/159)
No Virologic Data at Week 24 Window		
Discontinued study drug due to AE or death ^e	2% (7/317)	0%
Discontinued study drug due to other reasons and last available HIV-1 RNA <50 copies/mL ^f	5% (16/317)	3% (5/159)
Missing data during window but on study drug	1% (3/317)	2% (3/159)

- Week 48 window is between Day 295 and 378 (inclusive).
- For subjects in the SBR arm who maintained their baseline regimen for 24 weeks and then switched to COMPLERA, the Week 24 window is between Day 127 and first dose day on COMPLERA.
- Predicted difference (95% CI) of response rate for switching to COMPLERA at Week 48 compared to staying on baseline regimen at Week 24 (in absence of Week 48 results from the SBR group by study design) is -0.7% (-6.4% to 5.1%).
- Includes subjects who had HIV-1 RNA ≥50 copies/mL in the time window, subjects who discontinued early due to lack or loss of efficacy, and subjects who discontinued for reasons other than an adverse event or death and at the time of discontinuation had a viral load value of ≥50 copies/mL.
- Includes subjects who discontinued due to adverse event or death at any time point from Day 1 through the time window if this resulted in no virologic data on treatment during the specified window.
- Includes subjects who discontinued for reasons other than an adverse event, death, or lack or loss of efficacy, e.g., withdrew consent, loss to follow-up, etc.

14.2 Pediatric Subjects

The pharmacokinetics, safety, and efficacy of RPV in combination with other antiretroviral agents was evaluated in a single-arm, open-label Phase 2 trial in antiretroviral treatment-naïve HIV-1-infected pediatric subjects 12 to less than 18 years of age and weighing at least 32 kg (TMC-C213). Thirty-six (36) subjects were enrolled with a median age of 14.5 years (range 12 to 17 years), and were 55.6% female, 88.9% Black, and 11.1% Asian. The majority of subjects (24/36) received RPV in combination with FTC and TDF. Of these 24 subjects, 20 had baseline HIV RNA ≤100,000 copies/mL. The baseline characteristics and efficacy outcomes at Week 48 are further described below for the 20 subjects.

The median baseline plasma HIV-1 RNA and CD4+ cell count were 49,550 (range 2060 to 92,600 copies/mL) and 437.5 cells/mm³ (range 123 to 983 cells/mm³), respectively. At

Week 48, 80% (16/20) of the subjects had HIV RNA <50 copies/mL, 15% (3/20) had HIV RNA ≥50 copies/mL, and one subject discontinued therapy prior to Week 48 and before reaching virologic suppression (HIV RNA <50 copies/mL). At Week 48, the mean increase in CD4+ cell count from baseline was 225 cells/mm³.

16 HOW SUPPLIED/STORAGE AND HANDLING

COMPLERA tablets are purplish pink, capsule shaped, film coated, debossed with “GSI” on one side, and plain faced on the other side. Each bottle contains 30 tablets (NDC 61958-1101-1), a silica gel desiccant, and a polyester fiber coil, and is closed with a child-resistant closure.

Store at 25 °C (77 °F), excursions permitted to 15 °C–30 °C (59 °F–86 °F) [See *USP Controlled Room Temperature*].

Keep container tightly closed.

Dispense only in original container.

17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Patient Information).

Posttreatment Acute Exacerbation of Hepatitis B in Patients Coinfected with HIV-1 and HBV

Severe acute exacerbations of hepatitis B have been reported in patients who are coinfecting with HBV and HIV-1 and who have discontinued products containing FTC or TDF [see *Warnings and Precautions (5.1)*]. Advise patients to not discontinue COMPLERA without first informing their healthcare provider.

Severe Skin Reactions and Hypersensitivity

Advise patients to immediately contact their healthcare provider if they develop a rash. Instruct patients to immediately stop taking COMPLERA and seek medical attention if they develop a rash associated with any of the following symptoms, as it may be a sign of a more serious reaction such as DRESS severe hypersensitivity: fever, blisters, mucosal involvement, eye inflammation (conjunctivitis), severe allergic reaction causing swelling of the face, eyes, lips, mouth, tongue, or throat which may lead to difficulty swallowing or breathing, and any signs and symptoms of liver problems, as they may be a sign of a more serious reaction. Patients should understand that if severe rash occurs, they will be closely monitored, laboratory tests will be performed and appropriate therapy will be initiated [see *Warnings and Precautions (5.2)*].

Hepatotoxicity

Inform patients that hepatotoxicity has been reported with COMPLERA and that monitoring for hepatotoxicity is recommended [see *Warnings and Precautions (5.3)*].

Depressive Disorders

Inform patients that depressive disorders (depressed mood, depression, dysphoria, major depression, mood altered, negative thoughts, suicide attempt, suicidal ideation)

have been reported with COMPLERA. Advise patients to seek immediate medical evaluation if they experience depressive symptoms [see *Warnings and Precautions (5.4)*].

New Onset or Worsening Renal Impairment

Inform patients that renal impairment, including cases of acute renal failure and Fanconi syndrome, has been reported in association with the use of TDF. COMPLERA should be avoided with concurrent or recent use of a nephrotoxic agent (e.g., high-dose or multiple NSAIDs) [see *Warnings and Precautions (5.5)*].

Bone Loss and Mineralization Defects

Inform patients that decreases in bone mineral density have been observed with the use of TDF. Assessment of bone mineral density (BMD) should be considered in patients who have a history of pathologic bone fracture or other risk factors for osteoporosis or bone loss [see *Warnings and Precautions (5.6)*].

Drug Interactions

COMPLERA may interact with many drugs and is not recommended to be coadministered with numerous drugs. Advise patients to report to their healthcare provider the use of any other prescription or nonprescription medication or herbal products, including St. John's wort [see *Contraindications (4)*, *Warnings and Precautions (5.7)*, and *Drug Interactions (7)*].

For patients receiving rifabutin, an additional 25 mg tablet of RPV (Edurant) once per day is recommended to be taken concomitantly with COMPLERA and with a meal for the duration of rifabutin coadministration.

Lactic Acidosis and Severe Hepatomegaly

Inform patients that lactic acidosis and severe hepatomegaly with steatosis, including fatal cases, have been reported. Treatment with COMPLERA should be suspended in any patient who develops clinical symptoms suggestive of lactic acidosis or pronounced hepatotoxicity [see *Warnings and Precautions (5.8)*].

Immune Reconstitution Syndrome

Inform patients to inform their healthcare provider immediately of any signs and symptoms of inflammation from previous infections, which may occur soon after anti-HIV treatment is started [see *Warnings and Precautions (5.9)*].

Dosing Instructions

Advise patients that it is important to take COMPLERA on a regular dosing schedule with food and to avoid missing doses. A protein drink is not a substitute for food. If the healthcare provider decides to stop COMPLERA and the patient is switched to new medicines to treat HIV that include RPV tablets, the RPV tablets should be taken only with a meal.

Pregnancy Registry

Inform patients that there is an antiretroviral pregnancy registry to monitor fetal outcomes in those exposed to COMPLERA during pregnancy [see *Use in Specific Populations (8.1)*].

Lactation

Instruct patients with HIV-1 infection not to breastfeed because HIV-1 can be passed to the baby in breast milk [*see Use in Specific Populations (8.2)*].

Patient Information
COMPLERA[®] (kom-PLUH-rah)
(emtricitabine, rilpivirine, tenofovir disoproxil fumarate)
tablets

Important: Ask your healthcare provider or pharmacist about medicines that should not be taken with COMPLERA.
For more information, see the section “What should I tell my healthcare provider before taking COMPLERA?”

What is the most important information I should know about COMPLERA?

COMPLERA can cause serious side effects, including:

Worsening of Hepatitis B virus (HBV) infection. Your healthcare provider will test you for HBV before starting treatment with COMPLERA. If you have HBV infection and take COMPLERA, your HBV may get worse (flare-up) if you stop taking COMPLERA. A “flare-up” is when your HBV infection suddenly returns in a worse way than before.

- Do not stop taking COMPLERA without first talking to your healthcare provider.
- Do not run out of COMPLERA. Refill your prescription or talk to your healthcare provider before your COMPLERA is all gone.
- If you stop taking COMPLERA, your healthcare provider will need to check your health often and do blood tests regularly for several months to check your HBV infection. Tell your healthcare provider about any new or unusual symptoms you may have after you stop taking COMPLERA.

For more information about side effects, see the section “**What are the possible side effects of COMPLERA?**”.

What is COMPLERA?

COMPLERA is a prescription medicine that is used to treat Human Immunodeficiency Virus-1 (HIV-1) in people weighing at least 77 lb (35 kg) who:

- have **never** taken HIV-1 medicines before, **and** who have an amount of HIV-1 in their blood (this is called ‘viral load’) that is no more than 100,000 copies/mL before they start taking COMPLERA,
- or**
- in certain people who have a viral load that is less than 50 copies/mL when they start taking COMPLERA, to replace their current HIV-1 medicines.

HIV-1 is the virus that causes AIDS (Acquired Immune Deficiency Syndrome). COMPLERA does not cure HIV-1 or AIDS.

COMPLERA contains 3 medicines (emtricitabine, rilpivirine, tenofovir disoproxil fumarate) combined in one tablet.

Emtricitabine (EMTRIVA[®]) and tenofovir disoproxil fumarate (VIREAD[®]) are HIV-1 nucleoside analog reverse transcriptase inhibitors (NRTIs). Rilpivirine (Edurant[®]) is an HIV-1 non-nucleoside analog reverse transcriptase inhibitor (NNRTI).

It is not known if COMPLERA is safe and effective in children less than 12 years of age or who weigh less than 77 lb (35 kg).

Who should not take COMPLERA?

Do not take COMPLERA if you also take:

- anti-seizure medicines:
 - carbamazepine
 - oxcarbazepine
 - phenobarbital
 - phenytoin
- anti-tuberculosis (anti-TB) medicines:
 - rifampin
 - rifapentine
- proton pump inhibitor (PPI) medicine for certain stomach or intestinal problems:
 - dexlansoprazole
 - esomeprazole
 - lansoprazole
 - omeprazole
 - pantoprazole sodium
 - rabeprazole
- more than 1 dose of the steroid medicine dexamethasone or dexamethasone sodium phosphate
- St. John’s wort (*Hypericum perforatum*)

What should I tell my healthcare provider before taking COMPLERA?

Before taking COMPLERA, tell your healthcare provider about all your medical conditions, including if you:

- have liver problems, including hepatitis B or C virus infection
- have kidney problems
- have a history of depression or suicidal thoughts
- have bone problems
- are pregnant or plan to become pregnant. It is not known if COMPLERA can harm your unborn child. Tell your healthcare provider if you become pregnant during treatment with COMPLERA.

Pregnancy Registry. There is a pregnancy registry for those who take COMPLERA during pregnancy. The purpose of this registry is to collect information about the health of you and your baby. Talk with your healthcare provider about how you can take part in this registry.

- are breastfeeding or plan to breastfeed. Do not breastfeed if you are taking COMPLERA.
 - You should not breastfeed if you have HIV-1 because of the risk of passing HIV-1 to your baby.
 - At least two of the medicines contained in COMPLERA can be passed to your baby in your breast milk.
 - Talk with your healthcare provider about the best way to feed your baby during treatment with COMPLERA.

Tell your healthcare provider about all the medicines you take, including prescription and over-the-counter medicines, vitamins, and herbal supplements.

Some medicines interact with COMPLERA. Keep a list of your medicines to show your healthcare provider and pharmacist when you get a new medicine.

- You can ask your healthcare provider or pharmacist for a list of medicines that can interact with COMPLERA.
- Do not start taking a new medicine without telling your healthcare provider. Your healthcare provider can tell you if it is safe to take COMPLERA with other medicines.

How should I take COMPLERA?

- Take COMPLERA exactly as your healthcare provider tells you to take it.
- **Take COMPLERA with food.** Taking COMPLERA with food is important to help get the right amount of medicine in your body. A protein drink does not replace food. If your healthcare provider decides to stop COMPLERA and you are switched to new medicines to treat HIV-1 that include rilpivirine tablets, the rilpivirine tablets should be taken only with a meal.
- Do not change your dose or stop taking COMPLERA without first talking with your healthcare provider. Stay under the care of your healthcare provider during treatment with COMPLERA.
- If you miss a dose of COMPLERA within 12 hours of the time you usually take it, take your dose of COMPLERA **with food** as soon as possible. Then, take your next dose of COMPLERA at the regularly scheduled time. If you miss a dose of COMPLERA by more than 12 hours of the time you usually take it, wait and then take the next dose of COMPLERA at the regularly scheduled time.
- Do not take more than your prescribed dose to make up for a missed dose.
- If you take too much COMPLERA, contact your local poison control center or go to the nearest hospital emergency room right away.
- When your COMPLERA supply starts to run low, get more from your healthcare provider or pharmacy. It is very important not to run out of COMPLERA. The amount of virus in your blood may increase if the medicine is stopped for even a short time.

What are the possible side effects of COMPLERA?

COMPLERA can cause serious side effects, including:

- **See “What is the most important information I should know about COMPLERA?”**

Severe skin rash and allergic reactions. Skin rash is a common side effect of COMPLERA. Rash can be serious. Call your healthcare provider right away if you get a rash. In some cases, rash and allergic reaction may need to be treated in a hospital. **If you get a rash with any of the following symptoms, stop taking COMPLERA and call your healthcare provider or get medical help right away:**

fever
skin blisters
mouth sores

redness or swelling of the eyes (conjunctivitis)

swelling of the face, lips, mouth, tongue or throat

trouble breathing or swallowing

pain on the right side of the stomach (abdominal) area

dark or “tea colored” urine

- **Severe liver problems.** In rare cases, severe liver problems can happen that can lead to death. Tell your healthcare provider right away if you get these symptoms: skin or the white part of your eyes turns yellow, dark “tea-colored” urine, light-colored stools, loss of appetite for several days or longer, nausea, or stomach-area pain.
- **Change in liver enzymes.** People with a history of hepatitis B or C virus infection or who have certain liver enzyme changes may have an increased risk of developing new or worsening liver problems during treatment with COMPLERA. Liver problems can also happen during treatment with COMPLERA in people without a history of liver disease. Your healthcare provider may need to do tests to check your liver enzymes before and during treatment with COMPLERA.
- **Depression or mood changes. Tell your healthcare provider right away if you have any of the following symptoms:**
 - feel sad or hopeless
 - feel anxious or restless
 - have thoughts of hurting yourself (suicide) or have tried to hurt yourself
- **New or worse kidney problems, including kidney failure,** can happen in some people who take COMPLERA. Your healthcare provider should do blood tests to check your kidneys before starting treatment with COMPLERA. If you have had kidney problems in the past or need to take another medicine that can cause kidney problems, your healthcare provider may need to do blood tests to check your kidneys during your treatment with COMPLERA.
- **Bone problems** can happen in some people who take COMPLERA. Bone problems include bone pain, softening, or thinning (which may lead to fractures). Your healthcare provider may need to do additional tests to check your bones.
- **Too much lactic acid in your blood (lactic acidosis).** Too much lactic acid is a serious but rare medical emergency that can lead to death. Tell your healthcare provider right away if you get these symptoms: weakness or being more tired than usual, unusual muscle pain, being short of breath or fast breathing, stomach pain with nausea and vomiting, cold or blue hands and feet, feel dizzy or lightheaded, or a fast or abnormal heartbeat.
- **Changes in your immune system (Immune Reconstitution Syndrome)** can happen when you start taking HIV-1 medicines. Your immune system may get stronger and begin to fight infections that have been hidden in your body for a long time. Tell your healthcare provider right away if you start having new symptoms after starting your HIV-1 medicine.

The most common side effects of rilpivirine, one of the medicines in COMPLERA, include:

- depression
- trouble sleeping
- headache

The most common side effects of emtricitabine and tenofovir disoproxil fumarate, two of the medicines in COMPLERA, include:

- | | |
|-------------|--------------------|
| • diarrhea | • depression |
| • nausea | • trouble sleeping |
| • tiredness | • abnormal dreams |
| • headache | • rash |
| • dizziness | |

These are not all the possible side effects of COMPLERA.

Call your healthcare provider for medical advice about side effects. You may report side effects to FDA at 1-800-FDA-1088.

How should I store COMPLERA?

- Store COMPLERA at room temperature between 68 °F to 77 °F (20 °C to 25 °C).
- Keep COMPLERA in its original container and keep the container tightly closed.
- Do not use COMPLERA if the seal over the bottle opening is broken or missing.

Keep COMPLERA and all other medicines out of reach of children.

General information about safe and effective use of COMPLERA

Medicines are sometimes prescribed for purposes other than those listed in a Patient Information leaflet. Do not use COMPLERA for a condition for which it was not prescribed. Do not give COMPLERA to other people, even if they have the same symptoms you have. It may harm them. You can ask your healthcare provider or pharmacist for information about COMPLERA that is written for health professionals.

For more information, call 1-800-445-3235 or go to www.COMPLERA.com.

What are the ingredients of COMPLERA?

Active ingredients: emtricitabine, rilpivirine hydrochloride, and tenofovir disoproxil fumarate.

Inactive ingredients: croscarmellose sodium, lactose monohydrate, magnesium stearate, microcrystalline cellulose, polysorbate 20 povidone, pregelatinized starch. The tablet film coating contains FD&C Blue #2 aluminum lake, FD&C Yellow #6 aluminum lake, hypromellose, iron oxide red, lactose monohydrate, polyethylene glycol, titanium dioxide, triacetin.
