Ciba-Geigy Corporation
Attention: John R. Hanagan, M.D.
556 Morris Avenue
Summit, NJ 07901

Dear Dr. Hanagan:

Reference is made to your supplemental new drug application dated June 29, 1992, submitted pursuant to section 505(b) of the Federal Food, Drug, and Cosmetic Act for Aredia (pamidronate disodium for injection).

The supplement provides for revisions in the PRECAUTIONS section of the package insert as requested in our approvable letter dated June 22, 1992.

We have completed our review of this supplemental application and it is approved, effective on the date of this letter.

Please submit twelve copies of final printed labeling (FPL) identical to the draft labeling. Marketing the product with FPL that is not identical to the draft labeling may render the product misbranded and an unapproved new drug.

We remind you that you must comply with the requirements set forth under 21 CFR 314.80 and 314.81 for an approved NDA.

Sincerely yours,

[Signature]

SUPPLEMENT APPROVAL
Pamidronate disodium is a white-to-practically-white powder. It is soluble in water and in 2N sodium hydroxide, sparingly soluble in 0.1N hydrochloric acid and in 0.1N acetic acid, and practically insoluble in organic solvents. Its molecular formula is C₇H₇NO₇P₂Na₂·5H₂O and its molecular weight is 369.1.

Inactive ingredients: Mannitol, USP, and phosphoric acid (for adjustment to pH 6.5 prior to lyophilization).

CLINICAL PHARMACOLOGY
The principal pharmacologic action of Anedia is inhibition of bone resorption. Although the mechanism of antiresorptive action is not completely understood, several factors are thought to contribute to this action. Anedia adsorbs to calcium phosphate (hydroxyapatite) crystals in bone and may directly block dissolution of the crystals and component of bone. In-vivo studies also suggest that inhibition of osteoclast activity contributes to inhibition of bone resorption. In animal studies, at doses recommended for the treatment of hypercalcemia, Anedia inhibits bone resorption apparently without inhibiting bone formation and mineralization. Of relevance to the treatment of hypercalcemia is the finding that Anedia inhibits the accelerated bone resorption that results from osteoclast hyperactivity induced by various tumors in animal studies.

In cancer patients who had minimal or no bony involvement who were given an intravenous infusion of 60 mg of Anedia over 4 or 24 hours, a mean of 51% (33.6%) of the drug was excreted unchanged in the urine within 72 hours. Body retention during the period was calculated to be a mean of 49% (range 20-68%) of the dose, or 29.3 mg (12-41 mg). The urinary-excretion-ratio profile after administration of 60 mg of Anedia over 4 hours exhibited biphasic disposition characteristics with an alpha half-life of 16 hours and a beta half-life of 27.2 hours. There are no human pharmacokinetic data for Anedia on the 80-mg dose or in patients who have either renal or hepatic insufficiency. The rate of elimination of Anedia from bone has not been determined.

After intravenous administration of radiolabeled Anedia in rats, approximately 50-60% of the compound was rapidly absorbed by bone and slowly eliminated from the body by the kidneys. In rats given 10 mg/kg bolus injections of radiolabeled Anedia, approximately 30% of the compound was found in the liver shortly after administration and was then redistributed to bone or eliminated by the kidneys over 24-48 hours. Studies in rats injected with radiolabeled Anedia showed that the compound was rapidly cleared from the circulation and taken up mainly by bones, liver, spleen, thyroid, and tracheal cartilage. Radioactivity was eliminated from most soft tissues within 1-4 days; was detectable in liver and spleen for 1 and 3 months, respectively, and remained high in bone, thyroid, and liver for 6 months after dosing. Bone uptake occurred preferentially in areas of high bone turnover. The terminal phase of elimination half-life in bone was estimated to be approximately 300 days.

Serum phosphate levels have been noted to decrease after administration of Anedia, presumably because of decreased release of phosphate from bone and increased renal excretion as parathyroid.
...and hormone levels, which are usually suppressed in hypercalceremia associated with malignancy, return towards normal. Phosphate therapy was administered in 30 of the patients in response to a decrease in serum phosphate levels. Phosphate levels usually returned towards normal within 7 to 10 days.

Urinary calcium and calcium and urinary hydroxyproline concentrations decreased and usually return to within or below normal after treatment with Aredia. These changes occur within the first week after treatment, as do decreases in serum calcium levels, and are consistent with an antireceptor pharmacologic action.

Hypercalcemia of Malignancy
Osteoclastic hyperactivity resulting in excessive bone resorption is the underlying pathophysiologic derangement in metastatic bone disease and hypercalcemia of malignancy. Excessive release of calcium into the blood as bone is resorbed results in polyuric and gastrointestinal disturbances, with progressive dehydration and decreasing glomerular filtration rate. This, in turn, results in increased renal resorption of calcium, setting up a cycle of worsening systemic hypercalcemia. Correction of excessive bone resorption and adequate fluid administration to correct volume deficits are therefore essential to the management of hypercalcemia.

Most cases of hypercalcemia associated with malignancy occur in patients who have breast cancer, squamous-cell tumors of the lung or head and neck, renal-cell carcinoma, and certain hematologic malignancies, such as multiple myeloma and some types of lymphomas. A few less-common malignancies, including vasculitis, mesothelial-projection tumors, and cholangiocarcinoma, have a high incidence of hypercalcemia as a metastatic complication. Patients who have hypercalcemia of malignancy can generally be divided into two groups, according to the pathophysiologic mechanism involved.

In humoral hypercalcemia, osteoclasts are activated and bone resorption is stimulated by factors such as parathyroid-hormone-related protein, which are elaborated by the tumor and circulate systemically. Humoral hypercalcemia usually occurs in squamous-cell malignancies of the lung or head and neck or in genitourinary tumors such as renal-cell carcinoma or ovarian cancer. Skeletal metastases may be absent or minimal in these patients.

Extensive invasion of bone by tumor cells can also result in hypercalcemia due to local tumor products that stimulate bone resorption by osteoclasts. Tumors commonly associated with locally mediated hypercalcemia include breast cancer and multiple myeloma.

Total serum calcium levels in patients who have hypercalcemia of malignancy may not reflect the severity of hypercalcemia, since concomitant hypophosphatemia is commonly present. Ideally, ionized calcium levels should be used to diagnose and follow hypercalcemic conditions; however, these are not commonly or rapidly available in many clinical situations. Therefore, adjustment of the total serum calcium value for differences in albumin levels is often used in place of measurement of ionized calcium; several nomograms are in use for this type of calculation (See DOSAGE AND ADMINISTRATION).

Clinical Trials
In one double-blind clinical trial, 52 patients who had hypercalcemia of malignancy were enrolled to receive 30 mg, 60 mg, or 90 mg of Aredia as a single 24-hour intravenous infusion if their corrected serum calcium levels were ≥20 mg/dL after 48 hours of saline hydration.

The mean baseline corrected serum calcium for the 30 mg, 60 mg and 90 mg groups were 13.8 mg/dL, 13.8 mg/dL, and 13.3 mg/dL, respectively.

The majority of patients (64%) had decreases in albumin-corrected serum calcium levels by 24 hours after initiation of treatment. Mean-corrected serum calcium levels at days 2-7 after initiation of treatment with Aredia were significantly reduced from baseline in all three dosage groups. At a result, by 7 days after initiation of treatment with Aredia, 40%, 61%, and 100% of the patients receiving 30 mg, 60 mg, and 90 mg of Aredia, respectively, had normal corrected serum calcium levels. Many patients (33%-53%) in the 60 mg and 90-mg dosage groups continued to have normal-corrected serum calcium levels, or a partial response (≥15% decrease of corrected serum calcium from baseline), at day 14.

In a second double-blind, controlled clinical trial, 65 cancer patients who had corrected serum calcium levels of ≥20 mg/dL, after at least 24 hours of saline hydration were randomized to...
receive either 60 mg of Aredia as a single 24-hour intravenous infusion of 7.5 mg/kg of Diodrane (lactobionate calcium) as a 2-hour intravenous infusion daily for 3 days. Thirty patients were randomized to receive Aredia and to receive Diodrane.

The mean baseline corrected serum calcium for the Aredia and Diodrane groups were 14.6 mg/dL and 13.8 mg/dL, respectively.

By day 7, 70% of the patients in the Aredia group and 41% of the patients in the Diodrane group had normal corrected serum calcium levels (P < 0.05). None of the patients in the Aredia group and 65% of the patients in the Diodrane group had normal corrected serum calcium levels (P < 0.01). Mean corrected serum calcium for the Aredia and Diodrane groups decreased from baseline values to 10.4 and 11.2 mg/dL, respectively, on day 7. At day 14, 43% of patients in the Aredia group and 18% of patients in the Diodrane group still had normal corrected serum calcium levels, or maintenance of a partial response. For responders in the Aredia and Diodrane groups, the median duration of response was similar (7 and 5 days, respectively). The time course of effect on corrected serum calcium is summarized in the following table.

* Comparison between treatment groups

In both trials, patients treated with Aredia had similar response rates in the presence or absence of bone metastases. Concomitant administration of flurosemide did not affect response rates.

Twenty-five patients who had recurrent or refractory hypercalcemia of malignancy were given a second course of 60 mg of Aredia. Of these, 40% showed a complete response and 30% showed a partial response to the retreatment, and these responders had about a 3 mg/dL fall in mean corrected serum calcium levels 7 days after treatment.

**INDICATIONS AND USAGE**

Aredia, in conjunction with adequate hydration, is indicated for the treatment of moderate or severe hypercalcemia associated with malignancy, with or without bone metastases. Patients who have either epidermoid or non-epidermoid tumors respond to treatment with Aredia. Volumes of saline hydration, an integral part of hypercalcemia therapy, should be increased promptly and an attempt should be made to restore the urine output to about 2 L/day throughout treatment. Mild or asymptomatic hypercalcemia may be treated with co-nutritional measures (i.e., saline hydration, with or without loop diuretics). Patients should be hydrated adequately throughout the treatment, but overhydration, especially in those patients who have cardiac failure, must be avoided. Diuretic therapy should not be employed prior to correction of hypovolemia. The safety and efficacy of Aredia in the treatment of hypercalcemia associated with hyperparathyroidism or with other non-tumor-related conditions has not been established.

**CONTRAINDICATIONS**

Aredia is contraindicated in patients with clinically significant hyperparathyroidism in Aredia or other bisphosphonates.

**WARNINGS**

In both rats and dogs, nephropathy has been associated with intravenous, bolus administration of Aredia. A 3-month study in rats found concave tubular changes including epithelial degeneration with intravenous doses 2.5 mg/kg, given once every two weeks. Following a recovery period (1 month), the degenerative changes were completely reversed. Focal necrosis of renal tubules was partially reversed.

In two studies conducted in dogs, Aredia was given as a bolus intravenous injection either daily for 1 month or once a week for 3 months. In the 1-month study, tubulo-interstitial nephropathy, tubular
Aredia™ pamidronate disodium for injection

degeneration and dilution occurred at 2 mg/kg. At recovery (1 month) the severity of these lesions was minimal or trace. Similar lesions (slight to marked severity) were noted in the 3-month study at 3 mg/kg and higher. However, no improvement of the lesions was observed following the 1-month recovery period.

Patients with hypercalcemia who receive an intravenous infusion of Aredia should have periodic evaluations of standard laboratory and clinical parameters of renal function.

Studies conducted in young rats have reported the disruption of dental enamel formation with single-dose administration of bisphosphonates. The clinical significance of these findings is unknown.

PRECAUTIONS

General

Standard hypercalcemia-related metabolic parameters, such as serum levels of calcium, phosphate, magnesium, and potassium should be carefully monitored following initiation of therapy with Aredia. Cases of asymptomatic hypophosphatemia (16%), hypokalemia (9%), hypomagnesemia (12%), and hypocalcemia (6-12%), were reported in Aredia-treated patients. Rare cases of symptomatic hypocalcemia have been reported during Aredia treatment. If hypocalcemia occurs, short-term calcium therapy may be necessary.

Aredia has not been tested in patients who have class III renal impairment (creatinine >5.0 mg/dL). Clinical judgement should determine whether the potential benefit outweighs the potential risk in such patients.

Laboratory Tests

Serum calcium, electrolytes, phosphate, magnesium, and creatinine, and CBC, differential, and hematoctrit/hemoglobin must be closely monitored in patients treated with Aredia. Patients who have preexisting anemia, leukopenia, or thrombocytopenia should be monitored carefully in the first 2 weeks following treatment.

Drug Interactions

Concurrent administration of a loop diuretic had no effect on the calcium-lowering action of Aredia.

Carcinogenesis, Mutagenesis, Impairment of Fertility

In a 104-week carcinogenicity study (daily oral administration) in rats, there was a positive dose-related relationship for benign adrenal pheochromocytoma in males (p < 0.00001). Although this condition was also observed in females, the incidence was not statistically significant. When the dose calculations were adjusted to account for the limited oral bioavailability of Aredia in rats, the lowest daily dose associated with adrenal pheochromocytoma was similar to the intended clinical dose. Aredia (daily oral administration) was not carcinogenic in an 80-week study in mice.

Aredia was nonmutagenic in four mutagenicity assays: Ames test, nucleus-anomaly test, sister-chromatid-exchange study, and point-mutation test.

In rats, decreased fertility occurred in first-generation offspring of parents who had received 150 mg/kg of Aredia orally; however, this occurred only when animals were mated with members of the same dose group. Aredia has not been administered intravenously in such a study.

Pregnancy Category C

Aredia has been shown to increase the length of gestation and parturition in rats resulting in an increase in pup mortality when given orally at daily doses of 50 and 150 mg/kg/day from before pregnancy until after parturition. When corrected for oral bioavailability, each daily dose is approximately 0.7 to 1.7 times the highest recommended human dose for a single intravenous infusion. Oral doses of 25 to 150 mg/kg/day during the period of gestation failed to demonstrate any teratogenic, fetotoxic, or embryotoxic effects in rats or rabbits. Animal reproduction studies have not been conducted with intravenously administered Aredia.

It is not known if intravenous Aredia can cause fetal harm when administered to pregnant women or if it can affect reproductive capacity. There are no adequate and well-controlled studies in pregnant women. Aredia should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Nursing Mothers

It is not known whether Aredia is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when Aredia is administered to a nursing woman.
Pediatric Use

Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

Transient mild elevation of temperature by at least 1°C was noted 24-48 hours after administration of Aradex in 27% of the patients in clinical trials.

Drug-related local soft-tissue symptoms (redness, swelling or induration and pain at the site of catheter insertion) were most common (18%) in patients treated with 90 mg of Aradex.

When all on-treatment events are considered, the rate rises to 41%.

Symptomatic treatment resulted in rapid resolution in all patients.

Uveitis was reported in 1 patient who had hypercalcemia of malignancy, another patient who had Paget's disease of bone, and a third patient who responded to indomethacin and topical steroid. Both of these patients received Aradex in uncontrolled studies.

Four of 82 patients (4.9%) who received Aradex during the 2 U.S. controlled hypercalcemia clinical studies were reported to have had seizures: 2 of whom had pre-existing seizure disorders. None of the seizures were considered to be drug-related by the investigators. However, a possible relationship between the drug and the occurrence of seizures cannot be ruled out.

At least 15% of patients treated with Aradex for hypercalcemia of malignancy also experienced the following adverse events during a clinical trial:

- General: Fluid overload, generalized pain
- Cardiovascular: Hypertension
- Gastrointestinal: Abdominal pain, anorexia, constipation, nausea, vomiting
- Genitourinary: Urinary tract infection
- Musculoskeletal: Bone pain
- Laboratory abnormality: Anemia, hypercalcemia, hypomagnesemia, hypophosphatemia

Many of these adverse experiences may have been related to the underlying disease state.

The following table lists the adverse experiences considered to be drug-related that occurred during comparative, controlled U.S. trials.

OVERDOSE
One obese woman (95 kg) who was treated with 285 mg of Aredia/day for 3 days, experienced high fever (39.5°C), hypotension (from 170/190 mmHg to 90/60 mmHg), and transient taste perversion, noted about 6 hours after the first infusion. The fever and hypotension were rapidly controlled with steroids.

If overdose occurs, symptomatic hypocalcemia could also result; such patients should be treated with short-term intravenous calcium.

DOSE AND ADMINISTRATION
Consideration should be given to the severity of as well as the symptoms of hypercalcemia. The recommended dose of Aredia in moderate hypercalcemia (corrected serum calcium of approximately 12.5–13.5 mg/dL) is 60–90 mg, and in severe hypercalcemia (corrected serum calcium >13.5 mg/dL), 90 mg, given as an initial, single-dose, intravenous infusion over 24 hours. Albumin-corrected serum calcium (Ca, mg/dL) = serum calcium, mg/dL + 0.8 (4.0 - serum albumin, g/dL).

Vigorous saline hydration alone may be sufficient for treating mild, asymptomatic hypercalcemia. Overhydration should be avoided in patients who have potential for cardiac failure or hypercalcemia associated with hematologic malignancies, the use of glucocorticoid therapy may be helpful.

A limited number of patients have received more than one treatment with Aredia for hypercalcemia. Retreatment with Aredia may be considered if hypercalcemia recurs. It is recommended that a minimum of 7 days elapse before retreatment, to allow for full response to the initial dose. The dose and manner of retreatment is identical to that of the initial therapy.

Preparation of Solution
Aredia is reconstituted by adding 10 mL of Sterile Water for Injection, USP, to each vial, resulting in a solution of 30 mg/10 mL. The pH of the reconstituted solution is 6.0–7.4. The drug should be completely dissolved before the solution is withdrawn. The daily dose must be administered as an intravenous infusion over 24 hours. The recommended dose should be diluted in 1000 mL of sterile 0.45% or 0.9% Sodium Chloride, USP, or 5% Dextrose Injection, USP. This infusion solution is stable for up to 24 hours at room temperature. Aredia must not be mixed with calcium-containing infusion solutions, such as Ringer's solution.

Note: Parenteral drug products should be inspected visually for particulate matter and discoloration prior to administration, whenever solution and container permit.

Aredia reconstituted with Sterile Water for Injection may be stored under refrigeration at 36–46°F (2–8°C) for up to 24 hours.

HOW SUPPLIED
- Vials: each contains 30 mg of sterile, lyophilized, pamidronate disodium and 470 mg of mannitol, USP
- Carton of 4 vials: NDC 0083-2601-04

Do not store above 86°F (30°C).

Caution: Federal law prohibits dispensing without prescription.

Summit, NJ 07901

Dear Dr. Hanagan:

Reference is made to your supplemental new drug applications dated May 5, 1992, submitted pursuant to section 505(b) of the Federal Food, Drug, and Cosmetic Act for Aredia ( pamidronate disodium).

The supplement provides for revisions in the package insert as requested in our letter dated April 23, 1992.

We have completed our review of this applications and it is approvable. Before the application may be approved, however, we request that you incorporate the following revisions into the package insert:

1. The third sentence of the first paragraph in the General subsection under the PRECAUTIONS section should be revised to read as follows:

"Rare cases of symptomatic hypocalcemia (including tetany) have been reported in association with Aredia therapy."

2. The fourth paragraph of the ADVERSE REACTIONS section should not be modified.

Within 10 days after the date of this letter, you are required to amend the application, or notify us of your intent to file an amendment, or follow one of the other options under 21 CFR 314.110. In the absence of such action FDA may take action to withdraw the application.
The changes indicated above cannot be legally implemented until you have been notified in writing that the application is approved.

Sincerely yours,

Solomon Sobel, M.D.

SUPPLEMENT APPROVABLE
Review and Evaluation of Clinical Data

1. Name of drug: Trade: Aredia
   Generic: Pamidronate disodium for injection

2. Dosage form and route of administration: Available in vials, each containing 30 mg of pamidronate and 470 mg of mannitol, USP. The drug is administered as i.v. infusion over 24 hours after reconstitution (in sterile Water for inj.) and dilution in normal saline (1L).

5. Summary evaluation:

   In this submission, the sponsor has responded to our letter of April 23, 1992, in which we recommended revision of the Adverse Reactions section of the labeling to acknowledge a case report regarding development of "persistent hypocalcemia and convulsions in a hypercalcemic myeloma patient treated with Aredia (30 mg/day) on two successive days. The sponsor was requested to replace the last sentence of the Adverse Reactions section of the current labeling with the following, "However, there has been a report of the development of persistent hypocalcemia and convulsion in a hypercalcemia myeloma patient following Aredia therapy (cumulative dose of 80 mg over 2 days)." The sponsor states that in place of our recommended sentence, the following will accurately portray the incidence of symptomatic hypocalcemia, "Rare cases of symptomatic hypocalcemia have been reported in association with Aredia therapy." This sentence will replace the third sentence of the first paragraph under subsection General of Precautions section of the current labeling (See the copy of the labeling with proposed revisions). The third sentence in the current labeling reads "One case of hypocalcemia with symptomatic tetany has been reported during oral Aredia treatment." The sponsor feels that the proposed sentence will encompass pleural reference of "several events" of symptomatic hypocalcemia.

This reviewer has no objection to sponsor's proposed change, provided the sentence is modified as follows: "Rare cases of symptomatic (including tetany) hypocalcemia have been reported in association with Aredia therapy." There seems to be no reason to believe that patients with juvenile osteoporosis (following p.o.
Aredia) or hypercalcemia myeloma patients are more likely to develop symptomatic hypocalcemia following Aredia therapy. As such, the reference to juvenile osteoporosis and myeloma in patients with symptomatic hypocalcemia may be omitted.
6. Conclusion and recommendation:

(1) Sponsor's proposed replacement of the third sentence of first paragraph under General subheading of Precautions section is acceptable, provided it reads as follows: "Rare cases of symptomatic (including tetany) hypocalcemia have been reported in association with Aredia therapy."
I favor rewording the replacement of (1) as follows:

Rare cases of symptomatic hypocalcemia (including tetany or seizures) have been reported in association with androgen therapy.
